Another consideration is the quality of life that the heart transplant will enable the potential recipient to lead.

"Most of the recipients selected for transplant are people who have lived very active lives and who have been very frustrated whenever they have been in bed for even a few days," Dr. Lunde said. "These individuals would rather, in their own words, 'take a chance' on a heart transplant than face the rest of their lives as a bedridden cardiac invalid.

"For such people, the possibility of being active again, even for a brief period, outweighs their concern about longevity," he explained.

In concluding Dr. Lunde said that "as surgery now considered radical becomes more common and as more vital organs are exchanged, distortions of personality can be expected since personality and self-image are so closely tied to body-image. We will simply have to be prepared to deal with the increase of psychiatric complications."

STANFORD -- The students, staff and volunteers of Stanford University Medical Center will hold their sixth annual art sbow May 11-21, the opening week coinciding with National Hospital Week.

The public is invited to visit the show, which will be set up in the first floor waiting areas of Stanford University Hospital.

Works will include oils, watercolors, acrylics, collages, drawings, sketches, prints, photographs, sculpture and crafts.

Five professional judges will select award winners in the various categories. The judges are Mrs. Dagmar Dern of Redwood City, a member of Peninsula Stitchery Guild and Bay Area Arts and Crafts; Ray Lorenzato and Gilbert Steed of San Mateo, both art teachers at the College of San Mateo; Mrs. Lyman Page of Palo Alto, a member of the Palo Alto Art Club; and Paul Engelcke of Palo Alto, a member of the Palo Alto Camera Club.

A "Most Popular" entry of the show will be chosen by Medical Center personnel.

STANFORD--Four faculty members of Stanford University School of Medicine were awarded Henry J. Kaiser Memorial Awards for excellence in teaching during graduation ceremonies yesterday at the Medical School.

The recipients are Dr. Paul Berg, professor of biochemistry; Dr. A. Kent Christensen, associate professor of anatomy; Dr. William P. Creger, associate professor of medicine and associate dean for student affairs; and Dr. Kenneth D. Gardner, Jr., assistant professor of medicine. Dr. Gardner has recently been appointed professor of medicine at the University of Hawaii School of Medicine.

Each of the award winners will receive a $600 prize.

The Henry J. Kaiser Memorial Fund was established in 1968. All medical students have the opportunity to vote for those faculty members whom they feel have outstanding teaching abilities. Final selection of those to be honored is made by a joint committee that includes both faculty and students.

FOR RELEASE MONDAY, JUNE 23, 1969

STANFORD -- A report by a Stanford University medical research team that Bright's disease, an inflammation of the filtering system of the kidneys, is caused by an immune reaction, brings every hope that useful treatment may be forthcoming.

The report, presented Monday at the International Congress of Nephrology in Stockholm, Sweden, described studies in rats showing that the kidney disease is caused by an antibody directed against the specific protein of a strain of streptococcus which has been associated with the disease in humans.

In earlier studies, the Stanford investigators had demonstrated that of nine streptococcal strains used to infect animals, only the strain that contained the specific protein caused Bright's disease or glomerulonephritis.

The fact that an immune reaction might cause the kidney inflammation has been suspected for some time. Just how the streptococci could account for the disease was poorly understood. It was clear that the streptococci did not cause it by direct infection.

Now that the disease is known to be caused by an immune reaction directed at the specific protein, it would be possible to synthesize that protein and use it as a vaccine to stimulate antibody response to prevent the disease. This, however, is a step that will require further research, the investigators said.

The report was presented by Dr. Kenneth L. Vosti, associate professor of medicine at the Stanford University School of Medicine. His collaborators included Dr. Lois H. Lindberg, a research associate, Dr. John C. Kosek, assistant professor of pathology, and Dr. Sidney Raffel, professor and chairman of the Department of Medical Microbiology. Their work was supported in part by grants from the National Institute of Allergy and Infectious Diseases of the National Institutes of Health.

In the past, Dr. Vosti said, it had been difficult to study the disease because observations were limited to patients who had already developed all the clinical symptoms of glomerulonephritis.

-more-

The use of the rat as an experimental model, which fulfilled many of the epidemiological, clinical, and laboratory features of Bright's disease, has made it possible to examine to a degree not previously described the mechanisms that may be operative in various stages of the disease, he added.

The Stanford researchers infected rats with streptococci isolated from the pharynx of a 12-year-old boy with acute kidney disease. Another group of rats was exposed to a different strain of streptococci removed from the excised tonsil of a child with no history of kidney disease.

Only the rats infected by the streptococcal strain removed from the patient with nephritis developed the disease. The clinical and immunopathological features of the disease in the animal model were identical to those in man, Dr. Vosti said.

The animals began to excrete protein in their urine and antibodies to the specific protein of the streptococcal strain were detected in the glomerular filtering apparatus of the kidney before being excreted in the urine.

The presence of these materials, analyzed through a series of highly sophisticated and elegant experiments described by Dr. Vosti, provide strong support for an immunologic disease.

It has been suggested that the immunologic disease may be brought about by two possible mechanisms, Dr. Vosti explained in an interview.

It is possible that the protein settles in the glomerular filtering apparatus of the kidney, and that a specific antibody reacts with it to form a toxic immune complex. Or the protein reacts with the antibody in the bloodstream to form the toxic complex which then settles in the kidney's filtering apparatus and blocks it. As the kidney eventually loses its filtering efficiency, the patient may die of uremic poisoning.

Bright's disease is a major cause of illness among children. About 10 per cent of those affected become chronic kidney patients, eventually requiring dialysis treatment or kidney transplants.

STANFORD--Concerned that the proposed ban on DDT for home use by 1970 may result in further contamination of the environment, two Stanford University pharmacologists have urged the director of the California Department of Agriculture to issue specific guidelines for the disposal of DDT and related chemicals.

In a letter to Governor Ronald Reagan and the director of the California Department of Agriculture, Dr. Sumner M. Kalman and Dr. Robert H. Dreisbach of the Stanford University School of Medicine, have suggested that the State Department of Agriculture be made responsible for collecting and disposing of these chemicals.

Both pharmacologists support the proposed ban of chlorinated hydrocarbons pesticides for home use, announced recently by the director of the California Department of Agriculture.

"We are concerned about the problem of disposal," Drs. Kalman and Dreisbach wrote.

"Many householders will want to get rid of chlorinated hydrocarbons. It is a job for experts. These compounds have to be destroyed by chemical oxidation or by combustion at extremely high temperatures in sealed containers.

"This cannot be done at home. The chlorinated hydrocarbons should not be disposed of by washing down the sink, toilet, sewer, septic tank, or by burial, by placing them into garbage or trash cans, or by introduction into any body of water.

"Such action will contribute to a further contamination of our environment."

The chemicals which concern the Stanford pharmacologists include DDT, DDD, dieldrin, aldrin, chlordane, heptachlor, benzene hexachloride, lindane, toxaphene, endrin, isodrin, mirex, kepone, thiodan, tedion, prolan, and bulan. All of them are hard chemicals known for their slow decay rate.

"We suggest that persons wishing to dispose of these hazardous materials (be directed) to take them to...representatives designated by the director of the Department of Agriculture," the pharmacologists said.

STANFORD--The Clinical Sciences Research Building at Stanford University School of Medicine was named Friday (JUNE 20) in honor of the late Joseph Donohoe Grant, one of San Francisco's most distinguished sons and a lifetime member of the University Board of Trustees.

Honored guests at the afternoon ceremonies in the courtyard of the Joseph D. Grant Building for Research in the Clinical Sciences were Mr. Grant's daughters, Mrs. Josephine Grant McCreery of San Jose and San Francisco and Mrs. Edith Grant Ordway of Los Altos, and many long-time friends of the Grant family.

Speakers introduced by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, were W. Parmer Fuller III, president of the Board of Trustees and Dr. Loren Chandler, former dean of the School of Medicine and a personal friend of Mr. Grant.

Mr. Grant, a leading California industrialist, financier and merchant, served as a lifetime member of the University Board of Trustees for 51 years. He was appointed to the board by Senator Stanford in 1891 at the age of 33.

The late Dr. Ray Lyman Wilbur, former president and chancellor of the University, wrote at the time of Mr. Grant's death in 1942 that "He was a dependable, faithful, loyal, and devoted Trustee--always available and always ready...he was interested in advancing the University and was never contented with considering his trusteeship as a mere custodianship."

Joseph D. Grant was born in San Francisco in 1858, the son of pioneer parents. After his attendance at the University of California, he entered Murphy, Grant & Company, the wholesale drygoods concern of which his father was a founder, and became president of the Company in 1904. The business was sold in 1912.

Mr. Grant was a leader and pioneer in three important fields of western industry--petroleum, steel, and hydro-electric power. He was first vice-president of the General Petroleum Corporation, president of the Columbia Steel Corporation, and chairman of the board of California-Oregon Power Co.

The public cause in which Mr. Grant was most active was the Save-the-Redwoods League where he served for 21 years as chairman of the board of directors. The J. D. Grant Grove in the Del Norte coast region is one lasting token of his enthusiasm for this movement.

The Joseph D. Grant Building for Research in the Clinical Sciences, located between the Hospital and School of Medicine wings of the Stanford University Medical Center, was dedicated in 1966. The six-million dollar building was financed in part by the University's PACE Program (Plan of Action for a Challenging Era) and government grants.

The four-story structure--three floors and a basement--covers 152,000 gross square feet of space and contains research facilities for the departments of Anesthesia, Genetics, Medicine, Obstetrics, Pediatrics, Preventive Medicine, Psychiatry, Radiology, and Surgery. It also includes the Lt. Joseph P. Kennedy, Jr. Laboratories for Molecular Medicine, which are dedicated to an attack on the problems of mental retardation on a broad front of scientific research, and facilities supported by NASA for research in the fields of space biology and biomedical instrumentation.

THOMAS CHARLES MERIGAN, JR., M.D.
BIOGRAPHICAL INFORMATION

At 35, Dr. Thomas C. Merigan is regarded as one of the leading investigators in animal and human interferon. He joined the Stanford medical school faculty in 1963, and became an associate professor of medicine and head of the division of infectious diseases two years later.

One of his most recent scientific accomplishments* was the discovery of a new approach to increasing the effectiveness of interferon inducers, the experimental drugs which may someday be used in humans to stimulate the body's defenses against disease.

In collaboration with Dr. Erik de Clercq, a Stanford postdoctoral research fellow, and a West German scientist, Dr. Fritz Eckstein of the Max Planck Institute for Experimental Medicine in Göttingen, Dr. Merigan demonstrated that the potency of RNA inducers could be enhanced substantially by making a change in their molecular structure.

Although Dr. Merigan emphasizes that the "efficacy of the modified substances has yet to be proved in experimental animals," the basic finding is believed to lead to the development of better drugs to make cells produce more interferon when needed, and hence to increase protection against viruses.

"It is not unusual for Dr. Merigan to be cautious and to understate his case when it comes to scientific matters," says a colleague who regards him as "an energetic man, extremely bright, and a living reference book on viral diseases."

Dr. Merigan, on the other hand, insists that one can never be sure about anything in scientific research, and he tells a story to prove his point.

Five years ago, according to the story, Dr. Merigan and his associates reported they had noted human interferon in the serum of children after a live-virus measles vaccination. They found that the children were resistant to primary smallpox vaccination in the period during which circulating interferon was present.

"It was later called to our attention," says Dr. Merigan, "that this observation was made by Erasmus Darwin in 1803 when he noted that cowpox failed to infect patients with measles."

---

*Reported to the New York Academy of Sciences, June 18, 1969.

-more-

Darwin, of course, did not mention interferon. It took more than 150 years for the cell protein to be discovered. But Darwin made an astute observation when he wrote that, "The contagion of the measles, if it be taken in sufficient time before the variolous fever comes on, stops the progress of the smallpox in the inoculated wound and delays it until the measles fever has finished its career."

In 1967, Dr. Merigan in collaboration with Dr. William Regelson of the Medical College of Virginia, found that pyran, a synthetic plastic substance, was a powerful interferon inducer, but it was not yet suitable for widespread clinical use because of its side effects.

A prolific writer and researcher, Dr. Merigan has numerous contributions to his credit in the fields of molecular biology, virology, and human genetics.

In 1966, working with Drs. Kenneth Gardner, Sidney M. Goldman, Samuel R. Walker, and Joan M. C. Bull, he showed that medullary cystic disease, a rare but infrequently recognized fatal kidney disease, was inherited.

Dr. Merigan is a native of San Francisco and a graduate of the University of California (B.A. with honors 1955 and M.D. 1958).

Before joining Stanford, he was a clinical associate at the National Heart Institute, Bethesda, Md. For a two-year period (1963-65) Dr. Merigan worked at the Palo Alto Veterans Administration Hospital where, with Dr. Peter Rowley, he established a division of human genetics.

Dr. Merigan is married and has one child born in 1964.

Presently he continues his work in studying and developing derivatives of the known synthetic interferon inducers and experimental antiviral agents at his Stanford laboratory.

"My experience leads me to be cautious in predicting the immediate clinical future for interferon treatment," wrote Dr. Merigan in a recent issue of Hospital Practice. Nevertheless, the latest findings are more encouraging than any of us had expected. Limited clinical trials will probably be under way within the next year or two. They should make important contributions to our understanding of the role of interferon mechanism in human disease.

"At present I feel there are enough unresolved problems with systemic induction of interferon to limit initial human experiments to patients with severe infections carrying a high morbidity or mortality. Diseases in this category would include encephalitis, hepatitis, and overwhelming vaccinia, variola, varicella or herpes disease.

"Under such circumstances patients would have much to gain, and the benefit would outweigh any possible danger from the inducer. If such tests showed that the inducer was safe to administer, then the approach could be extended to more benign ailments of the respiratory tract or intestines.

"Patients with tumors, neurological diseases, autoimmune conditions that may be of viral etiology could also be early candidates for interferon therapy.

"We stand on the threshhold of an era that should see chemotherapeutic and other nonimmunologic methods for control of virus infections in humans become as commonplace as the use of antibiotics against bacterial infections."

Dr. Erik de Clercq, 28, is a postdoctoral research fellow in medicine at the Stanford University School of Medicine. A native of Belgium and a 1966 graduate of the University of Leuven Medical School, he joined the Stanford division of infectious diseases in 1968 to pursue his fundamental research in interferon induction under Dr. Thomas C. Merigan, Jr., one of the nationally known researchers in animal and human interferon.

Dr. de Clercq, who is in the United States under the sponsorship of the Belgian government and an Eli Lilly International Fellowship, began to investigate interferon inducers in 1965 under Prof. P. de Somer at the Rega Institute for Medical Research of the University Leuven. At Stanford these studies are now being extended to new, more potent derivatives of known synthetic interferon-inducing drugs and tests of their efficacy against viral diseases. (See earlier Stanford release dated 6-18-69.)

(ADVANCE) FOR P.M RELEASE WEDNESDAY, JUNE 18, 1969

NEW YORK -- Two Stanford University medical researchers in collaboration with a West German scientist have discovered a new approach to increasing the effectiveness of interferon inducers, the experimental drugs which may someday be used in humans to stimulate the body's defenses against disease.

The researchers told the meeting of the New York Academy of Sciences today that changes in the molecular structure of available interferon-inducing chemicals could produce greater antiviral protection than now possible.

Interferon is a complex protein manufactured in the body in response to infection and believed to hold the key to protection against a host of diseases ranging from measles and hepatitis to the common cold. Though the body produces the substance as a natural defense against infections, often it is not available rapidly enough or in large enough quantities to halt the spread of disease. Scientists are studying chemicals to prime the body's production of interferon.

The Stanford researchers said they used a synthetic form of a double-stranded ribonucleic acid (RNA), a genetic material found in living cells, and tested its effectiveness by comparing it before and after it was modified chemically.

From a relatively inactive chemical, the substance produced a significant increase in antiviral activity when it was modified and tested in laboratory human cell cultures, the Stanford researchers said.

Although the efficacy of the substance has yet to be proved in experimental animals, the basic finding is believed to pave the way to important progress in molecular pharmacology in terms of man's ability to modify interferon-inducing drugs in a favorable way to get the most useful therapeutic effect.

Presently, one of the problems with almost all types of double-stranded RNA interferon inducers is that they are broken down by the cell's enzymatic machinery too rapidly to have a prolonged therapeutic result.

The Stanford researchers are Dr. Erik de Clercq, postdoctoral research fellow from the University of Leuven, Belgium, and Dr. Thomas C. Merigan, associate professor and head of the Division of Infectious Diseases at Stanford University School of Medicine. Their work was supported by the National Institutes of Health.

The chemical used by the Stanford investigators is designated as poly r ASUS (a thiophosphate analogue of poly r AU which is a copolymer of riboadenylic acid and ribouridylic acid). It was developed for other purposes by Dr. Fritz Eckstein of the Max Planck Institute for Experimental Medicine in Göttingen, West Germany.

Dr. Merigan became interested in the chemical because of its reported resistance to cell enzymes. He suggested to Dr. Eckstein that the chemical might have potent interferon-inducing properties, and the German investigator agreed to ship a quantity of the drug to Stanford for the laboratory experiments.

-more-

The key difference in the strength of the modified chemical lies in the substitution of sulphur atoms in the place of oxygen atoms. This crucial change makes the compound more resistant to degradation by cellular enzymes, Dr. de Clercq explained.

Cells, treated with the modified drug, became 100 to 10,000 times more resistant to viruses compared to cells treated with the parent compound, and there was a 2- to 20-fold increase in interferon production.

The modified substance, Dr. de Clercq said, proved to be equal or better than the most active synthetic interferon-stimulating RNA available today. This RNA is a combination of polyriboinosinic and polyribocytidylic acids. Its interferon-inducing properties were discovered by scientists at the Merck Institute for Therapeutic Research in West Point, Penn.

"The tremendous increase in activity of a modestly active interferon-inducing compound by chemical modification is an encouraging development," Dr. de Clercq commented. "We believe we can achieve even better results when we study modifications of the most active compounds currently available."

Dr. Merigan agreed that one could make the same kind of molecular change in the most active materials available that should increase their interferon-inducing activity several orders of magnitude.

Asked if he would anticipate side effects with the modified drugs, Dr. Merigan said that this is an area that would require investigation.

"Effects such as toxicity as well as the therapeutic ratio (the practically effective dosage related to toxic dosage) will have to be determined," he said. "But we are very enthusiastic about going ahead with studies in animals to see if these modified RNA's have a better antiviral activity and therapeutic ratio than other currently studied experimental drugs."

He said that this kind of a rationally conceived pharmacological manipulation represented a new attack on the problems of interferon research.

"We believe that having alternative methods in interferon induction is tremendously important as it is likely that each clinical problem--in man or animals--will differ and, therefore, it will be critical to have drugs that will give some patients long-lasting protection and others high-level but transient protection," Dr. Merigan said.

Interferon was discovered a little more than a decade ago by the late Alick Isaacs and Jean Lindenmann, working at the National Institute of Medical Research in England. Although Isaacs immediately saw its great potential as a weapon against virus infections, it took several years of research work by investigators in many laboratories all over the world before clinical studies became possible.

Today interferon's natural role in defeating viruses is well documented and, now with the latest Stanford research finding, its application to human medicine has been moved a step closer.

STANFORD--Stanford University School of Medicine presented awards to seven graduating students at the annual senior class convocation Sunday evening (JUNE 15).

Diplomas were presented to 54 men and 5 women, members of the sixth class to complete Stanford's medical curriculum, which was inaugurated when the Medical School moved from San Francisco to the Stanford campus in 1959.

The diploma of William B. Ross, member of the class who was killed April 28 while on a mountain climbing expedition in Nepal, was accepted by his sister, Miss Vieno Ross of Malibu, California.

At the convocation, Frank West Bertram received the Dr. and Mrs. Joseph Fife Surgery Award, given annually to the outstanding student in surgery.

Walter Leroy Henry received the Robert H. Alway Book Award. Named in honor of Dr. Alway, dean of the Medical School from 1958 to 1964, the Book Award is given to a student who has "availed himself especially well of the Stanford five-year plan."

Gil Drake Tolan received the L. A. and Marian S. Hopkins Award in Dermatology.

The winner of the Lowell A. Rantz Memorial Award "to the student who has distinguished himself in the field of infectious diseases" was Rudolph Harvey Johnson.

The Harold K. Faber Pediatric Award was presented to Daniel Wohl Rosenn. This award is in recognition of outstanding accomplishments in pediatrics and of potential as a contributor to child health.

Henry Fredric Epstein received the Borden Undergraduate Research Award in Medicine given by the Borden Company Foundation, Inc., to the senior student who has completed the "most meritorious" research during his medical training.

Dr. Bernard W. Nelson, associate dean for student affairs, presented the awards, and Dr. Harold K. Faber, emeritus professor of pediatrics, announced the recipient of the award named in his honor.

Virginia Josephine ("Soo") Borson Wright received the Upjohn Achievement Award, given by the Upjohn Company to the senior exhibiting "outstanding clinical performance."

Miss Wright, who is president of the class, presented the annual Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine to Dr. Allen B. Barbour, assistant professor of medicine and head of the division of ambulatory medicine, who had also received the award last year.

The faculty address was delivered by Dr. Barbour, and, following his address, Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, administered the Declaration of Geneva and presented the diplomas.

Award winners and their parents' names and addresses are listed below:

CALIFORNIA -- Torrance: Rudolph Harvey Johnson, Mr. and Mrs. Harvey Russell Johnson
4114 West 177th Street

-- Berkeley: Virginia Josephine Borson Wright, Dr. and Mrs. Harry J. Borson
244 Alvarado Road

-more-

MARYLAND -- Cumberland: Walter Leroy Henry, Mr. Walter Henry, 205 South Street
NEW YORK -- Bronx: Henry Frederic Epstein, Mr. and Mrs. Kenneth A. Epstein
55 Knolls Crescent
OREGON -- Astoria: Gil Drake Tolan, Dr. and Mrs. William Burget, 25 W. Kensington
PENNSYLVANIA -- Kingston: Daniel Wohl Rosenn, Mr. and Mrs. Max Rosenn, 177 James Street
TEXAS -- Austin: Frank West Bertram, Mrs. Frank Bertram, 2302 Bonita.

The 59 members of the graduating class of Stanford University School of Medicine did not "swear by Apollo the physician, by Aesculapius, Hygeia and Panacea and take to witness all the gods and all the goddesses" when they received their diplomas this year.

They did take the Hippocratic Oath, but in its most recent form, that adopted in 1948 at a general assembly of the Organization Mondiale de la Sante, meeting in Geneva.

In taking the modernized ethical promise, each young M.D. said, in part: "I will solemnly pledge myself to consecrate my life to the service of humanity....I will practice my profession with conscience and dignity; the health of my patient will be my first consideration....I will not permit considerations of religion, nationality, race, party politics or social standing to intervene between my duty and my patient....' even under threat I will not use my medical knowledge contrary to the laws of humanity...."

Class President, Soo Borson Wright, who was the winner of the Upjohn Achievement Award for "outstanding clinical performance," explained why she chose the newer oath: "In clear language it unmistakably dedicates you to service. It is something I can take seriously, particularly because portions of the ancient oath which sound foolish in the context of modern medicine have been omitted, and political and social considerations which are relevant today have been included."

"Besides," she added, "it seems to me that among medical students there is very little interest in tradition for tradition's sake anymore.

But the taking of any oath at all was the carrying on of tradition, and in choosing the Declaration of Geneva, the Class of 1969 started what may become a new tradition.

STANFORD--Dr. Count D. Gibson, Jr., a nationally recognized leader in community health program administration, has been appointed professor and chairman of the Department of Community and Preventive Medicine at Stanford University School of Medicine.

Announcement of Dr. Gibson's appointment was made today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school.

Dr. Gibson joins the Stanford faculty following 11 years as professor and chairman of the Department of Preventive Medicine at Tufts University School of Medicine in Boston. At Tufts he was co-director of that school's Comprehensive Community Health Action Program, a project oriented toward maximum participation of various communities in meeting the health needs of their impoverished people. Pilot project sites for the program, which was initiated in 1965, were Columbia Point, a low-income housing development in Boston, which Dr. Gibson directed, and an almost exclusively Negro rural county in Mississippi.

In announcing Dr. Gibson's appointment, Dr. Glaser noted that the new department chairman "has clearly demonstrated that he is a leader in his ability to work with a disadvantaged community in developing effective medical care programs and to do so in a way that permits these programs to be used to learn more about the problems of administering health care to disadvantaged people. His organization and direction of the Columbia Point project is without equal.

"Under Dr. Gibson's leadership, the area of preventive medicine at Stanford will be expanded to meet new responsibilities in the community health field."

Prior to its expansion the Department of Preventive Medicine was headed by Dr. Rodney R. Beard, professor of preventive medicine. Dr. Beard will continue to play an important role in the department and will head the division of preventive medicine within the larger department. Other divisions and their heads are: Division of Biostatistics, Byron W. Brown, Ph.D.; Division of Clinical Social Work, David M. Kaplan, Ph.D.; Division of Community Medicine, Dr. Gibson.

Dr. Gibson is a native of Georgia where he received both his B.S. (1942) and M.D. (1944) degrees from Emory University in Atlanta. His internship and residency were served at Columbia-Presbyterian Medical Center in New York. He also served with the U.S. Army medical corps for two years.

While at Tufts, Dr. Gibson has been active on the Governor's advisory board for the Massachusetts Welfare Department and the review committee of the Massachusetts Department of Comprehensive Health Planning. He also served as a delegate to the White House Conference on Health in 1965.

Dr. Gibson is a member of many professional societies including Phi Beta Kappa and Alpha Omega Alpha, the American Board of Internal Medicine, the American College of Physicians, and the American Public Health Association.

STANFORD -- Eight fifth-year and three fourth-year medical students at Stanford University School of Medicine have been elected to Alpha Omega Alpha, the national honor medical society.

The new members, who were formally presented at the annual senior class convocation (June 15) by Dr. Roy H. Cohn, professor of surgery at Stanford, are: Frank West Bertram, Jack Greene Copeland III, Walter Leroy Henry, David Clifford Hueter, Daniel Carlyle Ihde, Alan Lee Rosenblum, Daniel Wohl Rosenn and Paul James Schunke of the fifth-year class; and Robert Clark Aber, Michael Paul Alexander and Bobbette Kraft Ranney of the fourth-year class.

Students and their parents' names and addresses are listed below:

CALIFORNIA	--	Los Angeles:	Alan Lee Rosenblum, Mr. and Mrs. Gordon Rosenblum 1423 N. Doheny Dr.
		Sacramento:	Paul James Schunke, Dr. and Mrs. Gustave B. Schunke, 6515 Greenbrae Rd.
ILLINOIS	--	Chicago:	Michael Paul Alexander, Mr. and Mrs. Joel L. Alexander 2147 West Farwell Ave.
MARYLAND	--	Cumberland:	Walter Leroy Henry, Mr. Walter Henry 205 South Street
MISSOURI	--	Kirkwood:	Bobbette Kraft Ranney, Mr. and Mrs. Robert Ranney, Jr. 434 N. Harrison Ave.
NEW HAMP.	--	North Hampton:	David Clifford Hueter, Mr. and Mrs. Clifford D. Hueter 60 Woodland Road
NEW MEXICO	--	Portales:	Daniel Carlyle Ihde, Mr. and Mrs. Ira Ihde 1131 S. Ave. G
PENNSYLVANIA	-	Easton:	Robert Clark Aber, Mr. and Mrs. Donald Aber 32 North 17th St.
	--	Kingston:	Daniel Wohl Rosenn, Mr. and Mrs. Max Rosenn 177 James St.
	--	West Chester:	Jack Greene Copeland, III, Mr. and Mrs. Jack Greene Copeland, Jr. Westtown - Thornton Rd., R.D. #5

STANFORD--Dr. Larry E. Heiges, Jr. of Lompoc is the new president of the Stanford Medical Alumni Association and Dr. Howard B. Kirtland, Jr. of San Diego is the new president-elect.

Dr. Heiges, who has been in general practice in Lompoc for 35 years, succeeds Dr. William H. Clark of Palo Alto. He will serve as president of the Association through June, 1970.

Dr. Heiges holds both the A.B. and M.D. degrees from Stanford University. He was graduated from the School of Medicine in 1933.

The new president has been active for many years in the blood bank program in California. A past president of the Santa Barbara County Medical Society, he was instrumental in the establishment of the Tri-County Blood Bank for Santa Barbara, Ventura, and San Luis Obispo counties. He has also served on the board of directors for both the California Blood Bank System and the American Association of Blood Banks.

Dr. Heiges has also been active in civic affairs. He is a past president of the Lompoc Rotary Club and is a member of the board of directors of both the Lompoc Boys' Club and the Boy Scout programs.

Re-elected for a three-year term on the Board of Governors of the alumni association were Dr. Winston W. Benner, '44, Oakland; Dr. Wilbur B. Hurlbut, '38, New York; Dr. Theodore W. Loring, '46, Eureka; Dr. Robert H. Quillinan, '42, Sacramento; and Dr. Victor Richards, '39, San Francisco.

Dr. Joseph W. St. Geme, Jr. of Palos Verdes was also elected to the Board of Governors, replacing Dr. Kirtland, '44, the new president-elect. Secretary-treasurer of the Association is Dr. David A. Rytand of Atherton, Bloomfield professor of medicine at Stanford.

At the recent annual medical alumni meeting, those members of the Class of 1919 who received 50-year awards were Dr. E. Forrest Boyd, Los Angeles; Dr. Thomas A. Card, Riverside; and Dr. Oscar F. Johnson, Sacramento.

Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine at Stanford University, has been elected to the Board of Directors of the National Fund for Medical Education.

The National Fund, which is headquartered in New York, was organized in 1949 under the sponsorship of a group of university presidents, the American Medical Association and the Association of American Medical Colleges. Its purpose is to mobilize sources of voluntary support for the nation's medical schools. Since 1951 it has awarded over $44 million in unrestricted, teaching and research grants to the schools.

Dr. Glaser has been dean of Stanford University School of Medicine since 1965. He is currently serving as chairman of the Executive Council and Assembly of the Association of American Medical Colleges.

STANFORD -- Collective violence in the United States may have achieved some social gains, but its use is now evoking counterviolence from opposition groups, causing greater tensions, divisiveness, and more violence, a special committee at Stanford University reported today.

Present conditions in this country favor collective violence, the committee warned. "We may anticipate even more of it unless we act both individually and collectively to end it."

The Stanford committee, chaired by Drs. David N. Daniels and Frank M. Ochberg, was formed after the assassination of Senator Robert F. Kennedy a year ago to study the causes of violence and prescribe cures.

Six task groups from the department of psychiatry of the Stanford University School of Medicine were formed to explore various areas--mass media violence, firearms control and violence, mental illness and violence, the phenomenon of assassination, crisis resolution and choice of violence, and the gun law controversy.

The committee's findings are presented in the current issue of "Stanford M.D.," the quarterly journal of the Stanford Medical Alumni Association.

The psychiatrists gave their diagnosis and these prescriptions on how the crisis of violence can be met:

--Americans must give up their ambivalent attitudes and make violence unacceptable. Our society, the psychiatrists believe, is mixed up. It condemns some forms of killing but it encourages war, capital punishment, and other collectively sanctioned eye-for-an-eye behavior. "As long as a nation values violence as an effective coping strategy, violent behavior will continue."

--Survival of American society lies not so much in conserving old values as in learning how to handle change and control its evolution, the committee feels. "Our primitive forms of aggression, our violence, bellicosity, and inclination to fight in a time of emergency work against our survival. We are now seeing an unprecedented acceleration of man-made changes, which call for accompanying changes in man, which we are having difficulty in making." Our crude efforts to contain violence is a reflection "of our preagricultural -age mentality straining to cope with an industrial-age environment."

--Americans have to shift the priorities of their lives. They must respond to groups having different views and needs. "Frustration plays a major role in engendering violence," the committee said. "The goals of personal dignity, self-respect, and self-determination for minority groups and communities in our society must become realistically attainable."

--Our politicians need to establish a better machinery for the expression of political grievances. The committee found that despite formalized feedback by periodic elections and our court system, the feeling of alienation between the people and our government still is significant. As a possible solution it recommends the addition of an ombudsman to the American political scene. The function of the office would be to impose a highly respected public official with investigatory powers between government bureaucracy and the public. Such a person might counter a growing feeling among dissenters and minorities that they are powerless to have their grievances dealt with by the establishment.

-more-

-- Police and judges should eliminate cruel social controls and punishment, and shift their emphasis on violence prevention through effective rehabilitation programs. "New therapeutic settings are necessary to approach the problems of violent offenders," the psychiatrists said. "Individual therapy specifically geared to the needs of such offenders, as well as group therapy techniques, must be further developed." Efforts should also focus on educational programs to reduce the frequency of damaging childhood experiences, and early detection and treatment of violent behavior.

--Parents must eliminate excessively punitive discipline for their children. "Parents who violently punish children for violent acts are teaching them how and in what circumstances violence can be performed with impunity."

--Americans must learn about the potential hazards of overpopulation and its contribution to violent behavior. Studies show that instigation of aggression in animals derives from conditions of high population density. Probably all species have an inherent level of tolerance for physical and psychological closeness to other members of their species. "We must consider the merits of personal family planning, and limiting the size of our families," the committee said.

--Guns account for most homicides and suicides in the United States, which leads all other industrialized countries in deaths by firearms. "Challenges of the complex urban society in which we live cannot be met with old frontier means of survival--every man protecting himself," the psychiatrists said. "More effective and uniform gun legislation can keep guns out of the hands of those who are likely to act impulsively."

--The mass media, especially movies and television, are powerful instruments for social learning in man. By their depiction of violence, these media have become a "school for violence" for Americans of all ages. With respect to children "evidence is accumulating that shakes any complacency one might feel about the child's ability to separate what he observes in TV fantasies from what he enacts in his own social behavior." The committee believes that reducing violence portrayal in the mass media, and promoting programming about the limits of violence and potential of nonviolent behavior, would be helpful along with possible federal regulation. One committee member commented: "Although the American child spends as many hours in front of the TV tube as he spends in school, we do not elect a board of TV education to approve the TV curriculum and to employ the superintendent of TV instruction. There is no code of ethics for the broadcaster comparable to the ethical code governing the classroom teacher."

The committee concluded that the maladaptive aspects of violence overshadow any possible adaptive ones in our society. "Our recommendations represent important steps that can and must be taken. The essential point is that each of us can take part in decreasing violence," the committee said.

STANFORD -- Stanford University Medical Center Auxiliary has donated over $20,000 to expand coronary care facilities at Stanford University Hospital, it was announced today.

Robert Murch, associate director of the Hospital, said the gift will be used to purchase and install a centralized bedside monitoring service for a 28-bed area. This will permit the area to function when necessary as a cardiac surveillance unit.

The cardiac surveillance unit is adjacent to the coronary care unit in the Hospital. Patients in the area are those admitted to the hospital with minor heart disorders or those who have recovered sufficiently from more acute problems and no longer require intensive treatment in the coronary care unit.

The Auxiliary gift will be used to remodel the nursing station with paneling and instrumentation for a centralized monitoring unit and to add monitoring equipment. It is expected that the remodeling will be completed by late summer.

In expressing gratitude to the Auxiliary for the gift, Murch praised the group's "constant concern for the needs of the Hospital in providing the best possible patient care." He pointed out that the Auxiliary has also given $7,000 this year to buy new draperies and curtains for the entire pediatric area of the Hospital.

Since the Medical Center was opened in 1959, the Auxiliary has given over $125,000 to the Hospital. Other projects include equipment for the intensive and coronary care units, the Hospital blood bank, and artificial kidney unit.

Each year the 1100 Auxiliary members give 75,000 hours of volunteer service to the Medical Center.

STANFORD--Stanford University School of Medicine is one of five medical schools which will collaborate on a new program aimed at improving the methods and content of graduate and continuing education of physicians, and strengthening ties between medical schools and communities.

The program will be supported by a two-year $548,000 grant from the Commonwealth Fund, and Carnegie Foundation of New York to be shared by the five medical schools--Stanford, Duke, Case Western Reserve, Johns Hopkins, and McGill.

Each of the schools will experiment with new methods of specialty training, development of closer relationships between physicians in practice and medical schools, and programs of continuing education for practicing physicians through their professional careers.

"Because our overall objective is to increase the quality of clinical medicine, we think that collaboration among schools is particularly valuable," says Dr. Halsted R. Holman, chairman of the Department of Medicine at Stanford. "This way, the results will incorporate experiences gained in five communities where medical care is organized differently." Dr. Holman will direct the program at Stanford.

Specifically, three areas of postgraduate education will receive attention:

--Clinical teaching in medical school, internship and residency will be given a critical review. Form, content, and time elements will be examined with regard to improving and reducing time and training, increasing opportunities for diversification, and improving the quality of teaching.

--A number of physicians at the residency level will be trained as "clinical scholars." They will develop skills in the principles and techniques of medical education, in statistical analysis as it applies to the study of natural history of disease and clinical investigation, and in research in such areas as clinical pharmacology, effectiveness of clinical practice methods in the community, and the economics and sociology of medical care. Later, these scholar-physicians will take positions on medical faculties to teach in the areas mentioned above, or they will join the staffs of community hospitals where they will conduct research, design and supervise internship and residency programs, and direct continuing education for community physicians.

--A physician-in-residence program will also be conducted at the five schools. It will enable private practitioners to return to university and community hospitals for one month each year to study the latest advances in clinical medicine.

"To share in the growth of medicine the practicing physician must have time to think, read and exchange ideas with his colleagues. This annual intellectual refurbishment will give him the opportunity to pursue those objectives and will help to break the isolation many physicians now suffer," Dr. Holman said.

Present efforts for continuing education of community physicians take the form of short-term lectures, demonstrations and scientific conferences. Most medical educators agree that these methods have been inadequate, and that adequate alternatives have not yet been developed.

STANFORD--Stanford University researchers will participate in a key phase of lunar soil analysis work assigned to NASA's Ames Research Center in Mountain View, California.

Stanford scientists Dr. Berthold Halpern, of the Department of Genetics, and Dr. Gordon Hodgson, geochemist at both Stanford University Medical Center and Ames, will test their portion of the hard-won samples of the moon's soil for the presence of porphyrin, the pigment which in animal life allows hemoglobin to capture and carry oxygen, and in plant life allows chlorophyll to capture light energy for the synthesis of sugars.

They will carry out this work in the specially equipped Lunar Laboratory at Ames as part of a consortium of sixteen scientists headed by Ames exobiologist Dr. Cyril Ponnamperuma.

If porphyrin compounds are found, they will have to be investigated further to determine the nature of their origin.

"While porphyrin compounds are a basis of life, not all porphyrins are biogenically formed," explained Dr. Hodgson. "They are composed of carbon, hydrogen and nitrogen, very abundant and ubiquitous elements.

"We think porphyrins can form as a result of energy shots in the atmospheres of carbon stars, and we have shown that they can arise under certain heat and lighting conditions on primitive planets.

"So we will have to look closely at the structure of any lunar porphyrins we do find," Dr. Hodgson continued. "Living organisms use a specific type of structure we can identify through induced optical activity. This is done by placing the (dissolved) material in a very intense magnetic field and observing the behavior of light which is passed through the solution."

There may be one other clue that the lunar porphyrins, if any, are indicators of extraterrestial life. This clue will be furnished if proteins, or fragments of proteins accompany the porphyrins, Dr. Hodgson said.

Proteins, however, are far less stable than porphyrins, which have been found on earth to be as old as 3.4 billion years.

STANFORD---Birth control pills seem to do more than just prevent pregnancies.

According to a Stanford University pathologist, contraceptive pills give the blood a greenish tint. As a result, a doctor can get false readings which might point to a disease a patient or a blood donor does not have.

Green plasma in a unit of donated blood usually indicates a bacterial infection of the blood and cannot be used in patients who need transfusions.

But now "green plasma should no longer suggest solely the presence of a pseudomonas organism producing a green pigment," writes Dr. Paul L. Wolf in the current issue of the New England Journal of Medicine.

"A prominent elevation in the blue-green plasma protein in many units of donated blood has been correlated with the usage of oral contraceptive pills," he says.

Dr. Wolf is an associate professor of pathology and director of clinical laboratories at Stanford University Medical Center. Co-authors of his report are Derek Enlander, Joanne Dalziel, and Janelle Swanson.

He believes the green color in the blood of women who take birth control pills is due to an increase in estrogen or female hormone. Estrogens are known to elevate green plasma protein in pregnant women, he says. Similarly, the oral contraceptive pills containing estrogen cause an increase in the copper-containing protein giving the green plasma color.

Because of this finding, Dr. Wolf suggests that blood banks subject green plasma to further tests before discarding it as infected.

"We believe that green plasma from blood donors who take contraceptive pills is suitable for transfusion usage," Dr. Wolf writes. "No untoward acute effects nor transfusion reactions have resulted from the utilization of these green plasma units from our blood bank."

STANFORD--All facilities of the Stanford University Hospital and Clinics will remain open on Monday, it was announced today.

Ken Dunkle, associate director for personnel of the Hospital, said that while he knew all employees will share in the excitement of the historic landing of Apollo 11 on the moon, it is essential that full medical services be maintained for the Palo Alto community.

Dunkle also said that the short notice of President Nixon's proclamation precluded the making of appropriate alternative arrangements.

President Nixon, in his statement Wednesday, acknowledged the need for organizations providing service to the public to remain open.

Wagenveld, Death Notice

Stanford University heart transplant patient Elton R. Wagenveld, 52, of Pleasanton, died suddenly this morning (SATURDAY, NOV. 29) at Stanford University Hospital. Mr. Wagenveld had been discharged from the Hospital three weeks ago but had been readmitted Friday for treatment of rejection. The exact cause of death is undetermined, pending an autopsy.

Mr. Wagenveld, a retired air traffic controller at Oakland Internation Airport, received his new heart July 16. He is survived by his wife, Ethel, two children, Vicky and Lester, and a brother.

STANFORD--Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine at Stanford University, has been elected to the Board of Directors of The Commonwealth Fund, a philanthropic foundation based in New York.

The announcement is being made simultaneously in the Fund's New York office today.

Founded in 1918, The Commonwealth Fund works largely in the field of medical education and community health.

Dr. Glaser currently serves as chairman of the executive council and assembly of the Association of American Medical Colleges, and is a member of the Board on Medicine of the National Academy of Sciences.

###

STANFORD--Patients at the Stanford University Hospital will be able to have wine with their noon and evening meals, with the approval of their physicians, beginning about the middle of August. The new choice on the menu was recently approved by the hospital board of directors after endorsement by the hospital medical board.

"For the patient whose condition permits, and who has his physician's approval, it has been shown that a small amount of wine not only adds satisfaction, but has an excellent therapeutic effect," said associate director of the hospital Robert W. Murch.

###

STANFORD--The Stanford University School of Medicine has named its dean's office conference room the J. E. Wallace Sterling Room in honor of Stanford's fifth president. The honor was bestowed in appreciation of Dr. Wallace Sterling's key role in bringing the School of Medicine to the University campus.

The move of the School of Medicine from San Francisco to the campus was accomplished in 1959, halfway through Dr. Sterling's 19-year presidency. He is now Chancellor of the University.

STANFORD--A major change in compensation policy for Stanford University Hospital employees was announced today by Dr. Thomas A. Gonda, director of the hospital.

The new policy, approved Saturday by the hospital board of directors, sets the hospital minimum wage for full-time employees at $450 a month, and calls for a standard increase of $40 a month for all other full-time hospital employees.

In addition, it provides the framework for other wage adjustments based on merit, promotion, and competition to enable the hospital to attract and retain outstanding employees at all levels, Dr. Gonda said.

The policy also contains many special fringe benefits.

This is the first major change in the hospital's direct compensation policy since Stanford University bought the former Palo Alto-Stanford Hospital and assumed responsibility for its management a year ago.

The wage policy will take effect retroactive to July 7, Dr. Gonda said.

Establishment of a higher minimum wage represents a 20 per cent increase over the current level of $376 a month. It is expected to have its greatest impact on more than 500 of the hospital's 1,600 full-time employees, some of them in the unskilled category.

Dr. Gonda said that at the former level "many of our workers had been forced to take more than one job to support their families."

"We believe it is essential to raise our minimum pay as rapidly and as high as possible to allow these employees to become more effective personally and occupationally," Dr. Gonda added.

The standard raise by a specific dollar amount is a departure from past hospital policy of annual percentage increases across the board.

"The raise is designed to give maximum benefit to employees at lower echelons. Increasing living costs for necessities have greater impact on them than on employees earning higher pay," Dr. Gonda commented.

In addition, the new policy contains key provisions for increases through promotion and merit.

"Merit can be individual, group, or institutional. And rewards for meritorious service are possible for each of these," Dr. Gonda said.

He stressed that the hospital "intends increasingly to use competitive pay primarily to retain outstanding people at all levels."

Dr. Gonda pledged that the hospital will increase its efforts to define better criteria for rewarding meritorious service than now available. He added that "a promotion policy that is fair to all employees must be worked out where it does not exist and will be continued where it does exist."

STANFORD--An increase in daily service rates beginning Tuesday (July 15) was announced today by the Stanford University Hospital.

"To meet increased costs of operation that reflect the continuing rise in costs of material and employee compensation, we find it necessary to increase our daily service rate," said Dr. Thomas A. Gonda, director of the hospital.

The daily rates, approved Saturday by the hospital board of directors, will be increased on the average of $7.50 for semi-private rooms for medical and surgical patients.

The new basic rates are: ward $55, semi-private $60, and private $68.50.

Dr. Gonda said that the hospital is attempting to reduce the time a patient spends in the hospital, and in some cases this will help offset some of the impact of the rate increase.

He said many physicians are taking advantage of the new pretesting program in which the hospital participates. This program enables certain patients to complete their medical tests at the hospital before being admitted. Such pretesting alone has reduced the length of hospitalization.

"The fact the Stanford University Hospital is highly specialized also enables us to take care of comparably serious illnesses in a shorter time," Dr. Gonda said. "We have statistics which show that our hospital compares favorably with other teaching hospitals in terms of length of time patients remain hospitalized."

The figures, compiled by the American Hospital Association, show that medical and surgical patients stay at the Stanford University Hospital an average 9.28 days compared to similar patients of 70 teaching hospitals, whose average stay is 11.37 days.

This was the first rate increase in Stanford University Hospital rates since fiscal 1967-68, when rates went up on the average of $6.50 a day.

(ADVANCE) FOR PM RELEASE SATURDAY, JULY 12, 1969

NEW YORK--Actual reconstruction of human skin by tissue grown under artificial conditions outside a living organism was reported here today by a Stanford University medical research team.

Dr. William T. Summerlin of the Stanford University School of Medicine told the meeting of the Society for Investigative Dermatology that skin grown in laboratory cultures for periods up to six weeks acted as a source of new skin cells in ulcerated or burn wounds.

Eight patients at Stanford University Hospital have been studied with the new experimental technique and have grown normal skin after receiving skin grafts grown in test tubes.

Four days after implantation of the cultured skin, epithelial cells had multiplied and formed a layer over the wound sites. On the third week, the cells in the transplant area had organized into a typical wound-healing type of epidermis with normal cells and structure. By the sixth week the patients' wounds had healed and were covered by normal skin.

"We have shown conclusively that epidermal cells can be maintained in tissue culture for periods up to six weeks and that they can be transplanted successfully," Dr. Summerlin said.

"The successful transplantation of cultured skin back to the original host demonstrates that epithelial cells retain their ability to differentiate," he said. "Many other kinds of cells rapidly become undifferentiated when they are grown in culture, forming a nonspecific cell type. But the epithelial cell keeps many of its natural qualities when it is maintained in the test tube."

The Stanford study was supported by grants from the National Institute of Arthritis and Metabolic Diseases of the National Institutes of Health. Dr. Summerlin's collaborators are Dr. Marvin A. Karasek, associate professor of biochemistry and research dermatology, and Miss Mary Ellen Charlton, senior research assistant.

It was Dr. Karasek's basic work that has led to the limited clinical application. In 1967, he demonstrated that cells taken from a rabbit and cultured for 14 days in a test tube grew normally when transplanted to the host animal. Dr. Karasek's finding ran counter to the belief among dermatologists that cultured adult skin cells had no ability to form a specific tissue. -more-

Until that time it was thought that skin would not survive for more than 14 days even under the common methods of preservation by refrigeration.

"The physiology of the cultured transplanted skin in the human patients is remarkably like that of any fresh skin grafts," Dr. Summerlin said. The newly formed skin has tolerated friction and other trauma, and has also shown perspiration signs.

He said that the Stanford patients have been studied for a period of 4 to 15 months after grafting, with no evidence of any abnormality in the graft sites.

Dr. Summerlin cautioned that "no widespread therapeutic uses can be suggested at this time," but noted that the potential clinical applications of the technique "are real and might come to pass after more patients are studied."

When it is certain that no basic changes are induced by long-term maintenance of skin in organ culture, then "banks" of cultured skin may become practical.

He noted that the technique should be considered as an additional approach to present methods of skin grafting. It may prove especially useful in severely burned patients whose own supply of fresh skin for grafting is limited.

The studies were conducted in the Guggenhime Clinical Research Center of the Stanford University Hospital which is supported by the NIH. Dr. Summerlin is at Stanford as a teaching and training fellow of the U.S. Public Health Service.

STANFORD--Stanford University Hospital is planning an increase in daily service rates beginning July 15, Dr. Thomas A. Gonda, director of the hospital, announced today.

The announcement is contained in a letter distributed to all patients scheduled for admission to the hospital.

The letter does not mention a specific amount. The amount of increase has yet to be determined by the hospital board of directors, Dr. Gonda said. He declined to comment on the proposed amount.

"In order to meet increased costs of operation that reflect the continuing rise in costs of material and employee compensation, we find it necessary to increase our daily service rate, effective July 15, the letter said.

"If you are still hospitalized on July 15, you will be informed by that time of the specific amount of increase in your daily service charge."

Daily service charges cover not only the usual hotel-type service such as room, linen, maintenance, housekeeping, and reservations, but also the many other services that are a routine part of hospital care.

Some of these are:

- round-the-clock general nursing services, including administration of medications, and special treatments.
- dietary services, including special meals, nourishments, therapeutic diets, or formulas ordered by the physician.
- a portion of the cost of services rendered by interns and residents.
- medical clerical services and preparation of medical records.

The hospital increased its daily service charges in fiscal 1967-68 on the average of $6.50 a day for semi-private rooms for medical and surgical patients. Present rates are: ward $55.50, semi-private $60, and private $67.50.

STANFORD--Stanford University provided more detailed plans today of its proposed Animal Research Center on Coyote Hill behind the Stanford campus.

Information about the Center was presented at the meeting of the Palo Alto Planning Commission last night. The Commission formally approved a request by the University Board of Trustees to divide the land area into parcels on which the Center will be built. The application next goes to the City Council for its approval.

The new facility will be constructed, owned, and managed by the University. Funds for the Center will be provided by a $281,000 grant from the National Institutes of Health to the School of Medicine and from Syntex Corporation.

Since its inception two years ago, the Animal Research Center has been planned as a joint project with the buildings of the University and of Syntex integrated and designed as a single facility.

Originally, the buildings for Syntex's use were to be built on land adjacent to the Stanford portion of the project and leased from the University. In reviewing the application to the Planning Commission, it was discovered that the project design, with the two facilities adjacent to each other, was not in strict compliance with the zoning ordinance. In order to comply, Stanford would have had to ask for a number of different variance approvals in order to accommodate the project design. Instead, the University and Syntex decided to change their own arrangements to insure that the plot plan for the Animal Research Center was in absolute compliance with the strictest legal interpretation of the ordinance.

"Plans and drawings of the new Center affirm the University's intention to maintain the rural atmosphere of the hill area," said Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Medical School.

Buildings of the new facility have purposefully been designed as small, low-rise structures to avoid excessive grading and destruction of the natural contours. Earthy color tones planned for the exteriors of the buildings will enable them to blend well with the surrounding area.

The new Center will be built among existing trees, most of which are being preserved, on approximately five of the 37 acres comprising the Coyote Hill area. The buildings and parking areas will take up only 6.28 per cent of the total square footage of the 37-acre plot. The remainder of the land will be maintained as rural property and will provide a grazing area for animals to be housed at the Center.

The site plan indicates the planting of numerous additional trees and the provision of ground cover and shrubs to conceal the roadway leading to the Center from below.

Architects for the Animal Research Center are Hawley and Peterson of Palo Alto.

-more-

Major components of the new facility will be a Primate Unit for behavioral science studies and a Mouse Unit for the raising of in-bred mice. The Central facility will provide examining rooms for the reception and treatment of animals, laboratories for the study of animal diseases, medical and research laboratories and support facilities. Other components will be quarantine and holding units.

Syntex will rent space from the University for small animal quarters, two laboratory buildings, and a housing unit for large animals. Syntex will utilize the Center exclusively for the testing of drugs and development of animal health products.

Director of the Animal Research Center will be Dr. Orland Soave, clinical associate professor of medical microbiology, and head of Stanford's present Animal Care Facilities.

"The use of animals for biomedical research is essential for the advancement of our ability to conquer diseases and elevate the standards of health throughout the world," Dr. Glaser says. "However, we must use them in a humane way and care for them in a manner consistent with today's knowledge of animal husbandry and veterinary medicine. The indoor-outdoor environmental design of the new facilities will enable us to house and treat animals in surroundings similar to their natural habitat.

"In addition," he stresses, "is the fact that animal research often benefits animals as much as it does man. The vast majority of our knowledge concerning the treatment of animal disease has resulted from their use in the study of human ailments. Such knowledge is then adapted to animal care."

One of the major research programs at Stanford requiring the additional facilities which the new Center will provide is the newly initiated program in comparative medicine.

This effort relates to the study of naturally-occurring diseases of animals that are similar, identical, or closely related to human ills. In such instances, the disease process can be observed from birth to death and every phase of its development studied. Animals so afflicted can be in-bred to determine the effect of selective breeding on the disease, and further, since the life span of animals is usually much shorter than that of man, the natural history of the diseases can be better defined.

"In spite of the tremendous advances in medicine in the past 50 years, there are still many unknowns--cures for cancer, diseases of the heart and circulation, and the problems of aging and mental retardation. Undoubtedly, animal research will play an important role in research directed toward the solution of these problems in the future," Dr. Glaser says.

"The new Animal Research Center should help us contribute significantly to this research," he says. "The cooperation of the University and Syntex in this project also provides a unique example of private industry and the academic community working side by side to benefit world health."

STANFORD--The National Multiple Sclerosis Society has announced grants to three Stanford University medical scientists to support research aimed at fighting the dread crippling disease.

Frank Casarella, chairman of the Board of Trustees of the Santa Clara County Multiple Sclerosis Society, presented a two-year postdoctoral fellowship of $16,720 to Dr. James R. Bamburg, a one-year fellowship of $12,500 to Dr. Jean-Jacques Vanderhaeghen, and an 18-month research grant of $4,995 to Dr. Marion E. Smith, who is a research biochemist and instructor in medicine at Stanford.

Dr. Bamburg, who comes to Stanford from the department of physiological chemistry at the University of Wisconsin, will take his advanced training under Dr. Eric M. Shooter, professor of genetics and biochemistry, and will study the structure and mechanism of nerve growth factor, a protein which stimulates growth and differentiation in nerve cells.

Dr. Vanderhaeghen, who received the M.D. and advanced degrees in neurology and pathology at the Free University of Brussels, Belgium, and who has been a visiting lecturer and research associate at Stanford for the past year, will study changes in nerve tissue that precede or follow an attack of multiple sclerosis. Specifically, he will be concerned with the nerve-insulating substance called myelin, whose destruction is a striking feature of the disease.

Dr. Smith will conduct a study of how cyanide induces loss of myelin, which it is hoped will throw more light on the loss of myelin through multiple sclerosis.

Multiple sclerosis is a chronic crippler affecting the brain and spinal cord. It usually strikes between the ages of 20 and 40. At the present time, an estimated 500,000 Americans suffer from it and related diseases.

Since the National Multiple Sclerosis Society was founded in 1946, it has granted over $11.5 million to support advanced research all over the world.

STANFORD--A new radioisotopic technique which provides sensitivity and specificity in the diagnosis of blood clots of the lungs has been developed by specialists in Nuclear Medicine at Stanford University School of Medicine.

Diagnosis of these clots, known to physicians as pulmonary embolism, has been hampered in the past, says Dr. Gerald DeNardo of Stanford, because earlier techniques were not sensitive enough, or involved some risk to the patient.

"This was unfortunate because pulmonary embolism accounts for 10 to 25 per cent of deaths of hospitalized patients," says Dr. DeNardo. "A safe, simple, accurate method for making this diagnosis was needed."

The new technique Dr. DeNardo and his associates have developed meets these requirements.

The new radioisotopic method provides photographs of the regions of the lung, showing, by means of two separate tests, how well each region is supplied by blood (perfusion) and air (ventilation). The perfusion test is performed by injecting radioactive particles into a vein and photographing their accumulation in the various regions of the lungs with a scintillation camera. In the ventilation test, the patient breathes radioactive xenon to obtain a photograph of the air flow to various regions of the lungs.

The perfusion test alone has proved to be a very sensitive means of detecting blood clots, but perfusion may also be abnormal in many diseases, such as pneumonia, emphysema, and asthma. With a ventilation test, the causes of the abnormal blood flow can be distinguished. "In embolism, ventilation is normal or nearly so, whereas, in other diseases of the lungs, ventilation is abnormal," explains Dr. DeNardo. "It is this combination of tests which assures early, accurate diagnosis. Accuracy and speed are important because effective, but widely differing, treatment can be prescribed once a diagnosis is established."

Neither test carries risks for the patient. "These tests produce approximately the same radiation as a standard chest X-ray," commented Dr. DeNardo.

His associates in developing the clinically practical technique are Dr. David Goodwin, assistant professor of nuclear medicine; Dr. Peter Dietrich, postdoctoral fellow in radiology; and Mrs. Beverly Bradley, a research assistant in the Division of Nuclear Medicine. The group is continuing to apply radioisotopic techniques to the study of lung function in an effort to expand their knowledge of the normal and abnormal physiology of the lung.

###

Mailed August 18, 1969.

#1

New ventilation test with radioactive xenon confirms or denies diagnosis of blood clot of the lung. Dr. Gerald DeNardo of Stanford University Medical Center watches tracing which tells him that patient (radioisotope technician Jeanni Page poses here) is receiving proper mixture of air and xenon, while research assistant Beverly Bradley records regional data and pictures with scintillation camera system.

#2 Blood flow study (at left) is abnormal (note areas of lesser intensity), whereas ventilation study (at right) reveals normal distribution of air flow. Normal blood flow and abnormal air flow confirm diagnosis of pulmonary embolism.

JANE DUFF 415: 321-5310

STANFORD--A 54-year old man from Detroit, Michigan became the 16th heart transplant patient tonight at Stanford University Hospital.

The recipient is Herman Scales, a negro. He received his new heart from an anonymous donor in a 4-1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

Scales is in fair condition.

Scales has suffered from congestive heart failure for the past 10 years. He and his wife, Theresa, owned and operated Scales Nursing Home in Detroit for 12 years before his heart condition forced Scales to retire. Mr. and Mrs. Scales have lived in Phoenix, Ariz. at 5434 E. Palomino Rd. for the past year and a half. The patient's mother, Mrs. Sadie Hodge, lives in Nashville, Tenn.

He was referred to Stanford the end of May.

In addition to Scales, Stanford has seven other surviving heart transplant patients.

STANFORD--Herman Scales, who received a transplanted heart at Stanford University Hospital last night, died this morning at 7 a.m. Doctors said that death was due to heart failure and high blood pressure in the pulmonary arteries. The high blood pressure in Mr. Scales' lungs was a result of his long-standing heart disease, and did not allow the body to receive sufficient oxygen.

Mr. Scales, 54, was the first negro recipient of a transplanted heart at Stanford.

SCIENCE WRITERS: Miss Luke's paper will be presented at 2:15 p.m. today at the Denver Hilton Hotel.

ADVANCE FOR P.M. RELEASE MONDAY, AUGUST 18, 1969.

STANFORD--A Stanford University medical technologist has demonstrated that a heat test is a reliable method of determining whether elevation of an enzyme in the blood is due to bone disease or liver disease.

The technologist, Miss Deirdre Luke, presented a report on her experiments of heat application to the enzyme alkaline phosphatase at a meeting of the American Association of Clinical Chemists in Denver. Her evaluation of the heat technique was conducted under the supervision of Dr. Paul L. Wolf, associate professor of pathology and director of the clinical laboratories at Stanford University Medical Center.

The Stanford scientists found that when a blood serum sample containing high alkaline phosphatas is heated to 56° C. for ten minutes the enzyme will become more than two-thirds inactivated if it is coming from a bone source. Bone diseases which commonly cause an enzyme increase are tumors originating in the bone, or cancers which have spread from another area to bone, and metabolic bone disease due to parathyroid conditions.

When liver disease is present, the alkaline phosphatase does not become inactivated as a result of heat treatment. The disease of the liver which most often causes a high level of the enzyme is ar obstruction of bile flow. Others are hepatitis, and cancer which has traveled to the liver.

The new test is simple, and because it is rapid, aids in the prescription of proper treatment, comments Dr. Wolf.

Miss Luke also described studies of a new chemical procedure for determining total alkaline phosphatase levels. The procedure would lend itself well to automation, suffers minimally from interference by other chemicals such as bile in blood, and is precise. Knowing the extent of serum alkaline phosphatase is important to diagnosis of many diseases.

Also, elevation of the enzyme does not necessarily indicate the presence of disease, says Dr. Wolf. It is natural for pregnant women and growing children to exhibit a high blood level of the enzyme, he explains.

STANFORD--Dr. Norman Kretchmer, professor of pediatrics at Stanford University School of Medicine, will receive the 1969 Borden Award of the American Academy of Pediatrics.

The Award, which will be presented at the Academy's annual meeting (Oct. 18-23) in Chicago, is given for outstanding achievement in research relating to nutrition and/or development of infants and children. Dr. Kretchmer will be honored for contributing to the understanding of biochemical processes which form the basis of distinctive cell differentiation in growth and development.

Specifically, Dr. Kretchmer and his co-workers at Stanford have demonstrated the changing patterns of enzyme activity during growth and development. He has also succeeded in clarifying the nature and intracellular localization of intestinal enzymes which assist the digestion and absorption of sugars in the intestinal tract. This discovery has been vitally important in treating children who cannot absorb food properly.

Dr. Kretchmer received the Ph.D. in physiological chemistry at the University of Minnesota in 1947, and the M.D. from the State University of New York College of Medicine in 1952. He recently returned to full-time teaching and research after ten years as Chairman of the Department of Pediatrics at Stanford.

STANFORD--Investigators from the Stanford University School of Medicine and the California State Department of Public Health have linked the virus that causes common measles to an invariably fatal form of encephalitis that affects as many as 200 children and young adults in the United States each year.

Research findings using modern techniques of electron microscopy and immunology point toward the measles virus as the cause of the disease, the investigators believe. Their studies have revealed the presence of viral particles within the nuclei of brain cells. Evidence pointing to measles has also come from other laboratories around the world. But the scientists acknowledge that final proof still is lacking until the virus itself can be successfully isolated in victims of the rare disease.

The disease is commonly known to physicians as Dawson's subacute inclusion-body encephalitis, after its discovery, in 1933, by Dr. James Dawson, now of the University of Minnesota. It hits young persons between 5 and 20. Symptoms include involuntary movements of the limbs, and profound mental changes. The blood of the victims also shows an unusually high prevalence of antibodies to the measles virus.

The Stanford and Berkeley investigators have postulated that the disease may be a consequence of a latent or chronic infection with a measles virus that has been reactivated. If their theory is correct, viruses from other diseases left over in the body may be the cause of some of man's most puzzling ailments. Among the ailments are multiple sclerosis, amyotrophic lateral sclerosis (Lou Gehrig's Disease) and certain leukemias.

These findings have been reported by Drs. Robert M. Herndon, John M. Freeman, Guy McKhann and Lucien J. Rubinstein of Stanford University, and Drs. Edwin H. Lennette and Robert L. Magoffin of the Viral Rickettsial Disease Laboratory at Berkeley. They were presented in part at the American Pediatric Society meetings earlier this year, in The Lancet, a British medical journal, and at a special conference held recently by the National Institute of Neurological Diseases and Blindness at Bethesda, Md.

-MORE-

The patients studied by the California group have all had measles in the past. The initial measles infection was usually uncomplicated and had occurred as many as eight years before the appearance of Dawson's encephalitis. All patients have had significantly higher levels of antibodies to the measles virus than do normal individuals, the investigators said.

In two children studied, gradual deterioration of personality and intellect spanned a nine-month and a one-year period, and was followed by more rapid and ominous deterioration for about a month. Both patients also had abnormal EEG (brain wave) patterns. Recently two more cases have been brought to the investigators' attention. One of these was "discovered early by an especially astute pediatrician," who had read of the earlier cases.

He linked minor personality changes, some loss of intellect, and muscle spasms with EEG abnormalities and referred the child to the Palo Alto group for study and therapy. "She is the least severely affected and still functioning child," the researchers said.

The Stanford physicians are treating the disease with antiviral drugs. Although they have been cautious to point out that treatment is "highly experimental," results so far are promising.

In 1964 another group of Stanford researchers (Drs. Rubinstein, Lloyd Silverman, and Carlton E. Schwerdt) successfully demonstrated viral organisms to be responsible for a rare degenerative and fatal disease in adults, called progressive multifocal leucoencephalopathy. Identical findings were reported simultaneously by a group of researchers at the University of Wisconsin. The condition results from the replication of a hitherto unsuspected viral agent in the nuclei of brain cells responsible for the formation and maintenance of nerve fiber sheaths.

Dr. Rubinstein, a neuropathologist, is professor and acting head of the Department of Pathology at Stanford. His associates include members of the Division of Neurology, and the Departments of Medicine, Pediatrics and Medical Microbiology. Their line of investigation has included electron microscope studies of brain biopsies from selected patients, to determine their fine structure and biochemical changes.

An important purpose of these studies is also to isolate and culture the suspected viruses and to develop rational and effective methods of treatment, Dr. Rubinstein said.

STANFORD -- A study of the patient with leukemia and the impact of the fatal disease on his immediate family will be launched by the Stanford University School of Medicine under a $23,265 grant from the American Cancer Society.

Purpose of the study is to improve clinical services currently offered to leukemic patients and their families by social workers at the Stanford University Medical Center, and elsewhere.

The project will be directed by Dr. David Kaplan, associate professor and head of the Division of Clinical Social Work. Participants will include Dr. Stanley Fischmann, assistant professor of psychiatry and pediatrics, who will study the reaction of the leukemic child to the illness. Other faculty members from the Department of Pediatrics and the Division of Social Work will assist.

Dr. Kaplan has a special interest in the subject and has co-authored with Dr. Donald G. Langley of the UC Medical School at Davis, the recent book "The Treatment of Families in Crisis."

"While medical progress has extended the lives of leukemic children, the illness is fatal and often has a devastating impact on their families," Dr. Kaplan said.

"The stress attending the illness is overwhelming as evidenced by high rates of divorce, suicide, mental illness, and the neglect of other members within the family."

Dr. Kaplan commented that previous studies by other workers have stressed the hospital experience of the child and his family, not the total impact of the illness. "Observations in the home have been neglected," he said. "As a result, the effectiveness of services offered by social workers to these struggling families is seriously limited."

The Stanford researchers will make careful observations of family reactions in the clinic, on the ward, in the home, and in the child's school. They hope to develop reliable criteria which will enable social workers to predict reactions as these families attempt to handle problems during the critical phases of the child's illness.

"The data will enable health workers to intervene effectively to protect all family members against the multiple stresses associated with chronic illness," Dr. Kaplan said. "The findings should also have broad application to families attempting to cope with other terminal illnesses."

STANFORD--Dr. Roger O. Egeberg, the newly appointed assistant secretary for Health and Scientific Affairs of the Department of Health Education and Welfare, will speak at the Stanford University School of Medicine Thursday (September 25).

Dr. Egeberg's topic will be "From Crisis to Crisis: The Federal Role in Health Research Education." It is his first major speech given at a medical school since Dr. Egeberg assumed the federal post earlier this summer.

The talk will be given at 4 p.m. in Room M106 of the Medical School. It is open to members of the local medical community, and the public.

Later in the evening, Dr. Egeberg is scheduled to address a joint dinner meeting of the Santa Clara and San Mateo County Medical Societies, and bring to local physicians up-to- date information on HEW plans for the future of health care. The joint dinner will be at 6:30 p.m. in the Cabana-Hyatt Hotel in Palo Alto.

STANFORD--The Mid-Peninsula Kidney Foundation has presented a gift of $1500 to Stanford University Medical Center for the establishment of a library of current literature on kidney diseases.

Announcement of the gift was made today by Mrs. Delano Large, foundation president of Palo Alto.

"Research is vitally important to the solving of the problems of kidney disease," Mrs. Large said. "This donation to Stanford will make the latest information on the advances being made in the treatment of kidney diseases available to all community physicians."

Funds of the local chapter of the kidney foundation are raised through local memberships, memorials, and profits from an annual Halloween "Trick-or-Treat" Candy Sale.

"It is gratifying and appropriate that patients in this community should benefit directly from contributions made by the community," Mrs. Large said.

ADVANCE FOR PM RELEASE WEDNESDAY, SEPTEMBER 17, 1969

Editors: Dr. Paul Wolf will present his paper at 5:45 p.m., Wednesday at the Palmer House in Chicago.

STANFORD--The effectiveness of a relatively new test, developed to detect infectious mononucleosis, "the kissing disease," was challenged today by a Stanford University pathologist.

The spot test, tried recently in two Stanford patients, indicated a positive diagnosis of infectious mononucleosis. But on further investigation, the two patients, both college-age males, turned out to have a more serious disease--lymphoma, cancer of the lymph gland tissue.

In another case, what appeared with the spot test to be mononucleosis was actually viral hepatitis.

Speaking at the meeting of the American Society of Clinical Pathologists in Chicago, Dr. Paul Wolf said "the test is too sensitive and other diseases can cause a positive result, leading to the wrong diagnosis."

Dr. Wolf is associate professor of pathology and director of the clinical laboratories at Stanford University School of Medicine. Co-authors of the paper he presented are Dr. Ronald Dorfman, co-director of surgical pathology at Stanford; Dr. James McClenahan, director of the student health service; and Frances Collins, a medical technologist at Stanford.

The test in question has been widely used by pathologists throughout the United States. It uses horse cells, and takes only two minutes to perform.

Dr. Wolf recommended that when a positive mononucleosis diagnosis is indicated, several other factors should also be taken into account: a careful medical history of the patient, physical examination results, the total "blood picture," and results of the more lengthy sheep cell test for infectious mononucleosis.

Dr. Wolf commented on recent studies which offer evidence of a relationship between infectious mononucleosis and lymphoma. A virus known as EB virus, and EB virus antibodies are found in both conditions. Both of the patients Dr. Wolf cited were tested for EB virus antibodies and had them.

The cause of infectious mononucleosis is not established for sure, but EB virus is suspected. Mono is called the kissing disease because it is sometimes transmitted that way. Contaminated drinking containers and food utensils is another way. It usually occurs where large groups of 15-to-25 year-olds associate, such as on college campuses.

"We don't know what kind of a relationship exists between mono and lymphoma," said Dr. Wolf. "One possibility is that young people get EB virus infection and turn it off by antibody production. Others do not build up enough antibodies and the infection becomes full blown, with malignant lymphomas resulting.

"But this is not at all clear," he said.

In an effort to learn more about the relationship, spot test results are being correlated with clinical findings and data from blood tests.

Stanford heart transplant patient Herman Joslyn, 64, died this afternoon at Stanford University Hospital. The cause of death is undetermined, pending an autopsy although Mr. Joslyn was being treated for a lung infection.

Mr. Joslyn, a retired airline pilot from Seattle, received his transplanted heart from an anonymous donor on Sept. 14. He was the 18th person to receive a transplanted heart at Stanford. Seven other patients survive, six of whom has been discharged from the hospital.

Mr. Joslyn is survived by his wife and a daughter, both of Seattle.

STANFORD--Stanford University Medical Center Auxiliary has made a gift of $13,500 to the Hospital for purchase of a fetal monitoring unit for the delivery room.

Announcement of the gift was made today by Auxiliary President Mrs. George E. Boyd, Los Altos.

The portable unit is similar to other methods of patient monitoring and records the rate and function of the heart of the fetus as it moves down the birth canal just prior to delivery. The recordings are taken by an external microphone and by scalp electrodes attached painlessly to the head of the fetus. This information is then fed to a central monitoring unit at the nurses station, enabling both doctors and nurses to detect any possible abnormality in the birth process. If signs of fetal distress are evident, the staff can begin procedures to ensure delivery of a healthy baby.

According the Dr. Robert C. Goodlin, associate professor of obstetrics and gynecology, and Dr. Philip Sunshine, associate professor of pediatrics, the use of this research facility will hopefully reduce the incidence of infant mortality and brain damage in newborns.

The auxiliary's gift will enable Stanford University Hospital to be one of the few hospitals in the West to offer the use of fetal monitoring to prospective mothers.

LIVINGSTON, CALIFORNIA--The Stanford University Medical Center is, by any yardstick, one of the finest in the country. Yet, like similar centers elsewhere, its facilities, until recently, have been available only to those lucky enough to live in the vicinity or wealthy enough to travel there.

To Wells Shoemaker, a second-year medical student, this is not enough. This outspoken and energetic young man and four other Stanford medical students have long been conscious that every rural corner of the country harbors scores of patients suffering because of inadequate medical care.

In Merced County, an area of 108,000 inhabitants, there is one doctor for every 1,750 people. This critical manpower shortage and long distances from farms and towns to hospitals and clinics in the larger cities seriously restrict health care delivery. Overworked doctors attempt to see as many as 60 patients a day, to say nothing of emergencies. The county has only one pediatrician to care for families with as many as 13 children. The understaffed public health system cannot manage all patients who need to be treated.

This was the challenge that moved Shoemaker and his fellow medical students into action early this summer. If the patients could not be brought to Stanford, he reasoned, then the medical center must be moved to the patient, leaving behind it a better informed people, and a medical faculty aroused to the problem.

Shoemaker gained the support of Dr. A. Frank Brewer, the Merced County health officer, and the local county medical society, and a physician's office was found in Livingston (pop. 3,000) to open a free clinic for migrant workers and low income persons living in the area. Dr. Brewer had been planning a night clinic for Livingston for several years, but has so far run into funding difficulties.

The office belongs to Dr. J. J. Wolohan, a 52-year-old general practitioner and the only doctor in Livingston for the past 23 years. Dr. Wolohan has let the students use his x-ray facilities, and laboratory three nights a week when the clinic normally operates. He is also one of several volunteer physicians from Merced, Turlock, Modesto, and the Stanford University School of Medicine who supervise the student's work.

The free clinic has seen more than 80 patients a week, with increasing loads expected during the peak of the harvest season. The Stanford students conduct interviews, give physical examinations, participate in immunization and screening programs, and treat patients under supervision of the licensed physicians. (Part of the student's work will count toward a Stanford ambulatory medicine requirement for clinical year students.)

-more-

Some patients, according to Shoemaker, receive extensive followup care and consultation. For example, a 10-month-old boy was picked up on routine check with severe anemia. Referred to the Livingston clinic, the baby was seen by a medical student and a professor of pediatrics. The anemia had no easy explanation, and the pediatrician took several blood smears back to a pediatric hematologist at Stanford. The blood specialist made a diagnosis of a rare hemoglobin defect. The child will be followed up at Stanford. Other patients have been seen by eminent specialists on gastrointestinal, cardiological, and neurological problems.

The students are assisted in their work by three bilingual community aides employed for the project by Office of Economic Opportunity funds through Central California Action Associates. They are Inez Acosta and Cecilia Montoya of Livingston, and Alice McWaters of Atwater.

Miss Acosta has been a licensed visiting nurse, and will enter formal nurses' training at Merced Hospital this fall. Miss Montoya was formerly employed in a medical office as a secretary and interpreter. Mrs. McWaters has had no formal training experience but has worked with many low-income persons who visit the clinic.

The three women, who received a crash course in community aide work by Miss Faustina Solis, director of the California Farm Workers Health Service, have become a vital part of the Livingston clinic. "They have become familiar with the kind of questions doctors ask, and make the history taking a smooth process," Shoemaker said. "They can recognize a patient's dissatisfaction, help him overcome his nervousness, and explain procedures professionally and gently."

Since the clinic got underway in June, it has been gaining recognition from Merced health authorities. Physicians and public health nurses are now referring patients to the Livingston clinic, especially pediatric patients because OEO-funded health programs in migrant camps do not cover babies under two.

"These are remarkable students," said Dr. Wolohan. "They are intelligent, have considerable knowledge of medicine, and are very mature particularly in dealing with people. Certainly, they know more about medicine than we did at the same stage of our training."

The community response has been positive, too, Dr. Wolohan added. "The people are interested in these young men and feel proud they have come to Livingston. There is a good community reaction all around."

Dr. Wolohan attributes this success to the student's skills of organization and sensitivity to community feelings. The students have arranged so that the clinic program is controlled by a local committee. The group is composed of members from the local Neighborhood Service Center, and the Livingston Community Action Council, Inc., which represents low income families.

The committee, according to Shoemaker, serves as a clearing house for improving the program and a sounding board for community reaction and complaints so that development of the clinic can progress in an orderly and professional manner. The group also gives guidance to health education efforts in the community and the family camps located near Livingston.

-more-

With the help of the California Farm Workers Service, the students are preparing a handbook, to be printed in Spanish and English, giving information about health care, immunization, and legal resources in the county. "We found that migrant workers are bombarded with a lot of confusing information from different agencies," said Hans J. Dankers, a Stanford premedical student from Woodside. "Many families often are eligible for medical care but are unaware of it. We think the handbook would be helpful to them."

The students are living in a ricketty, 100-year-old former schoolhouse near Livingston which rents for $50 a month. They receive a small stipend from the medical school and a $15-a-week food allowance from the Central California Action Associates. The program was started with a $250 budget for operating expenses, some of which was used to buy drugs and laboratory supplies. Pharmaceutical companies also contributed drugs.

In addition to Shoemaker and Dankers, students contributing their skills to the project are Joe Neal, Larry Crapo, and Patrick Sullivan. Miss Betsy Anderson, a graduate of the Stanford School of Nursing, worked at the clinic earlier this summer, before joining the staff of the Stanford University Hospital. Other medical students have travelled from Stanford to Livingston to assist.

Neal, a fifth-year student and the most experienced in the group, is a versatile former Stanford lineman who distinguished himself during the 1962-64 football seasons. In 1966 Neal went to Vietnam with the International Voluntary Service to obtain a personal view of public health in underprivileged areas.

"You don't have to go to Vietnam to see that we, too, have areas of real medical poverty," Neal said. "The main thrust of medicine has been along basic research lines. There has been a certain amount of neglect for people in the process. But this is changing and the impetus has come not from the medical profession but from students."

Dr. Reo Campbell, assistant public health officer for Merced County, commented: "The Stanford students have shown a real desire to do something constructive and people appreciate it. The experience will be beneficial to the students, too, because it gives them early exposure to the practice of medicine outside the esoteric and sometimes stilted university hospital environment."

He expressed hope that with more programs of this type, students may see the need for medical services in small communities and perhaps return there after their training.

"There is a real need for community practice because many patients in the rural areas are being neglected," Dr. Campbell said.

STANFORD--A 45-year-old housewife from Logan, Utah became the 17th heart transplant patient today at Stanford University Hospital.

The recipient is Betty Johnson. Mrs. Johnson received her new heart from an anonymous donor in a 4-1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

The patient is in satisfactory condition.

Mrs. Johnson has suffered deterioration of the heart muscle for the past two and a half years. She was referred to Stanford Aug. 12.

Mrs. Johnson and her husband, Homer, have four children, Jay 23, Jeff, 19, Jim, 16, and Jarid, 11. Mr. Johnson is chairman of the Department of Educational Administration at Utah State University. The Johnsons are natives of Tacoma, Washington.

In addition to Mrs. Johnson, Stanford has six other surviving heart transplant patients.

STANFORD--The Stanford University School of Medicine today announced it has extended its deadline to end its affiliation with the San Mateo County General Hospital to June 30, 1970.

In a letter to Robert B. St. Clair, chairman of the San Mateo County Board of Supervisors, Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, said that the decision to maintain resident physician coverage until June at the County Hospital was taken in the interest of patients.

"I would like to emphasize that our sole reason for extending our program is to provide you with adequate time to make other arrangements for physician coverage of those patients who are admitted to your institution," Dr. Glaser wrote.

"It is our direct concern for the welfare of your patients that has led us to the extension."

Earlier, the medical school had announced it would pull its residency training programs out of County General by December 31.

"The decision to disaffiliate was reached reluctantly," Dr. Glaser said, "and was based on our considered view that it would not be possible to maintain satisfactory house staff and student programs because of the major change in your patient population.

"Despite the necessity to terminate the present arrangement, we stand ready in the future to review any proposals that you wish to make."

STANFORD--Two Nobel prize-winning scientists have been named to endowed professorships at Stanford University School of Medicine.

They are Dr. Arthur Kornberg, Emma Pfeiffer Merner Professor of Biochemistry, and Dr. Joshua Lederberg, Joseph D. Grant Professor of Genetics. The two endowed chairs were made possible by a gift from the Gustavus and Louise Pfeiffer Research Foundation of New York and a bequest from the estate of Joseph D. Grant.

"I take particular pleasure in announcing these two appointments," Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, said today. "Dr. Kornberg and Dr. Lederberg are and will continue to be leaders on the frontiers of medical knowledge and understanding in the basic medical sciences. It is especially fitting, therefore, that they should be named to endowed chairs bearing the distinguished names of Emma Pfeiffer Merner and Joseph D. Grant."

Dr. Kornberg received the Nobel Prize in 1959 for synthesizing DNA (deoxyribonucleic acid), the genetic material believed to determine the heredity of all living things. Dr. Lederberg was awarded the Nobel Prize in 1958 for his work in bacterial genetics.

Emma Louise Pfeiffer was born in Cedar Falls, Iowa in 1860 and lived there for 63 years. After the death of her husband, David C. Merner, a pharmacist, she moved to California to be with her family in Palo Alto. Her brother, Gustavus, and his wife established the Pfeiffer Research Foundation of New York 27 years ago. The Merner and Pfeiffer families have had ties with Stanford for over three generations. Mrs. Merner is described by those who know her intimately as a gracious and lovable woman of strong influence in a family with long matriarchal and philanthropic traditions.

The Joseph D. Grant Professorship in Genetics honors one of San Francisco's most distinguished sons. Mr. Grant, a leading California industrialist, financier and merchant, served as a lifetime member of the University Board of Trustees for 51 years. He was appointed to the board by Senator Stanford in 1891 at the age of 33.

Earlier this year the Clinical Sciences Research Building at the School of Medicine was named in honor of Mr. Grant. Attending the ceremonies were his daughters, Mrs. Josephine Grant McCreery of San Jose and San Francisco, and Mrs. Edith Grant Ordway of Los Altos.

Joseph D. Grant was born in San Francisco in 1858, the son of pioneer parents. After his attendance at the University of California, he entered Murphy, Grant & Company, the wholesale drygoods concern of which his father was a founder, and became president of the Company in 1904. The business was sold in 1912.

Mr. Grant was a leader and pioneer in three important fields of western industry--petroleum, steel, and hydroelectric power. He was first vice-president of the General Petroleum Corporation, president of the Columbia Steel Corporation, and chairman of the board of California-Oregon Power Co.

The public cause in which Mr. Grant was most active was the Save-the-Redwoods League where he served for 21 years as chairman of the board of directors. The J. D. Grant Grove in the Del Norte coast region is one lasting token of his dedication to this movement.

STANFORD--Alcohol is a dangerous drug, not only in its acute effects on behavior, but in its tendency to cause addiction, a Stanford pharmacologist said last night.

"The so-called Establishment is uptight about drugs these days, but they're thinking of drugs that are new in our culture--heroin, marijuana, LSD," Dr. Dora B. Goldstein told a class at Stanford University School of Medicine. "They shouldn't forget about alcohol."

"Alcohol should not only be included in the roster of drugs to worry about, but by all accounts, it should be at the top of the list. The estimates for the number of alcoholics in this country run about 100 times higher than for heroin addicts--about 60,000 for heroin and 6 million for alcoholics."

Dr. Goldstein addressed a group of school administrators and science teachers attending a class on drug abuse. The class is being presented as a public service by the Department of Pharmacology at Stanford and the Santa Clara Valley Science Teachers Association.

"I do not think it at all feasible or desirable to try to stop people from drinking, but adult and child alike should be aware of the factors that increase the probability of alcohol abuse," Dr. Goldstein pointed out.

All the effects of alcohol on behavior are a result of depression of brain function, the speaker said. Alcohol knocks out different parts of the brain in order, and the ones that go first are the self control circuits--the parts of the brain that damp down behavior and prevent over-reaction.

"This is why the person who is tipsy appears elated and stimulated. As the concentration of alcohol in the blood becomes higher, depression is obvious."

"To avoid dangerous alcohol blood levels it is important to know about the rates of onset and disappearance of the behavioral effects of alcohol," Dr. Goldstein explained.

"The rate of onset is determined by how fast the drug gets from the stomach to the brain. The peak concentration of alcohol in the blood is seen about 30 minutes after drinking if the stomach is empty. If food is taken before or with the alcohol, this peak is not reached for two hours and then, because it is being broken down in the body during those two hours, it will not reach the high blood concentration of the alcohol consumed on an empty stomach."

"A cocktail before dinner is the way to get the most out of a given amount of alcohol," she continued. "It is also the most damaging way to drink."

A given amount of alcohol affects small people more than larger ones, she pointed out. The smaller person has a smaller volume of body water, so although he is carrying the same amount of alcohol as someone larger, its concentration is higher. The smaller person also has a smaller liver and so he has less capacity to oxidize alcohol and its effects wear off more slowly.

Another chronic effect of alcohol in humans is malnutrition, Dr. Goldstein pointed out.

-more-

"Alcohol is a source of calories and it is taken in amounts comparable to those of other foods. So people who drink heavily eat very little."

"Vitamin deficiency diseases, which have become very rare in this affluent country, are still seen in alcoholics. Most of the degenerative effects of alcohol on the brain and perhaps those of the liver are due to malnutrition rather than to alcohol directly."

Dr. Goldstein said that the stages through which an incipient alcoholic passes are recognizable and predictable. She pointed out the danger signals--frequent drunkenness, preoccupation with alcohol, black-outs, morning drinking and solitary drinking.

"All these signs indicate that the individual is unwilling or unable to keep his alcohol intake down to harmless levels," she said.

"Alcohol can very probably be used in moderation without any harm. But alcoholism is a disease we do not know how to cure so we had better learn to prevent it," Dr. Goldstein said. "I think the best hope for this is to learn how to get pleasure from alcohol without getting drunk. People should know how much alcohol they can safely drink and how long its effects will last and should be watchful for signs of dependence on and preoccupation with alcohol."

"We should also try to modify the attitudes of ourselves and others so we don't glorify drinking or urge people to drink more than is good for them," she concluded.

STANFORD -- Interns and residents at Stanford University Hospital will meet with hospital and medical school officials Monday night (Oct. 27) to discuss proposals seeking salary increases and improved benefits.

No figures have been disclosed, but the Stanford University Hospital House Staff Association has suggested substantial annual salary increases across the board and improved fringe benefits for all interns and residents, according to Stephen I. Marglin, president of the group.

In addition, the Association has been seeking extension of benefits to cover certain postdoctoral fellows at the medical center. The group is also asking that salary increases become retroactive to July 1.

Dr. Thomas A. Gonda, director of the Hospital, said the hospital is wholly dependent on patient revenue, and it recently has increased its daily rates to meet rising labor costs.

In addition, the sharp cutbacks in federal support for medical education and research, have put a tremendous fiscal burden on the Stanford University School of Medicine which supports a significant portion of the house staff salaries, he said.

Stanford's 140 interns and residents already received increases in July. Their new stipend schedule provided an annual increase of $700 for interns and annual increases of up to $1,000 for residents.

Interns and beginning residents also received a new benefit--a $500 annual allowance per dependent child up to a maximum of $1,000.

The salary schedule adopted in July was based on proposals submitted to the Hospital by the House Staff Association. The proposal that was agreed upon was believed to provide the most equitable distribution of available funds in the current hospital budget, Dr. Gonda said.

Present intern base salaries after the July increase are $6,000 per year before dependency allowances are added. Annual salaries for resident physicians are: first-year, $6,500; second-year, $7,000; third-year, $7,500; fourth-year, $8,000; and fifth-year, $8,500. Allowances for their dependents are also additional.

STANFORD -- The California Chapter of the Myasthenia Gravis Foundation has made a grant of $1,000 to Dr. William W. Hofmann of Stanford University School of Medicine for continued research with the serious disease which weakens muscles used in breathing and swallowing.

Current investigation into myasthenia gravis, a disorder in the transmission of impulses from the nerves to the muscles, suggests "that possibly because of an abnormality in the thymus gland, some cells of the body manufacture substances which work against the muscles and also against a process of neuromuscular transmission," explains Dr. Hofmann.

The Foundation has contributed toward his work since the late 1950's; he will use the current gift for patient care and for partial support of a research fellow.

Noted biophysicist and biologist Dr. Oleg Jardetzky has joined the faculty of Stanford University School of Medicine as professor of pharmacology.

He comes to Stanford from the Merck Institute for Therapeutic Research in Rahway, New Jersey, where he had been executive director since 1968. Prior to that he served as director of the department of biophysics and pharmacology in the Merck Sharp and Dohme Research Laboratories.

Most of Dr. Jardetzky's research has been in the area of biological application of nuclear magnetic resonance, a method which permits detailed study of interactions between drugs and receptors. In 1964 he was chairman of the First International Conference on Magnetic Resonance in Biological Systems, held in Boston. From 1959 to 1966 he was an assistant professor at Harvard Medical School and a Senior Fellow of the United States Public Health Service. This year he was chairman of the first Gordon Conference on molecular pharmacology. He received his degrees from Macalester College (B.A. 1950) and the University of Minnesota (M.D. 1954 and Ph.D. 1956).

Dr. Jardetzky is married to the former Norma Wade of Virginia. They are making their home in Palo Alto.

STANFORD---In the past the Stanford University School of Medicine, like most of America's prestige schools, has been content to wait for applications from qualified black and brown students.

Few applied. Even fewer were admitted.

As a result blacks, and students of Mexican-American or American-Indian ancestry became solitary figures in the medical school's classrooms and laboratories.

For example, of the 300 medical students enrolled in the school in 1968-69, only three were blacks and one of them was from Nigeria.

This year the Stanford picture has changed drastically. After extensive recruiting, 12 students (7 blacks and 5 Mexican-Americans) have entered medical training at the school. Ten of the students are part of a special program designed for minorities. Two others have been admitted to the school through the regular channels.

The group represents the largest number of minority students in the school's history.

To facilitate development of the special program, the medical school increased its entering class size from 64 to 74 students, with 10 places available each year to minorities, said Dr. Bernard W. Nelson, associate dean for student affairs.

In addition, the faculty has decided that minority applicants will be evaluated by criteria more relevant to their needs and background. Their selection will be made by a committee on minority admission composed of minority group representatives and faculty.

The medical school has pledged to provide funds to aid minority students who are unable to finance their education and tutoring help for those who need it.

Dr. Nelson explained that minorities are caught in the vise of insufficient funds and inadequate secondary education and that recruitment and assistance in medical school must be directed to an easing of these pressures. His comments appear in an interview in "Stanford M.D.," the quarterly magazine of the Stanford Medical Alumni Association.

"We have come to realize," he said, "that in selecting minority applicants we must consider other factors than just Medical College Admission Test scores.

"It is widely recognized that a student's accomplishment in medical school is principally determined by his own ability, knowledge, and motivation. Although grade point averages and test scores generally reflect these qualities, they may be inaccurate in indicating the basic ability and motivation of a minority student where social, financial, and regional barriers must be considered."

In general then, black and brown students cannot, at the present time, be measured by the same standards, Dr. Nelson said. Until the educational handicaps are removed, beginning from the elementary level, minority students will always be at a disadvantage in a competitive sense. But this does not mean that they cannot qualify for admission nor that they will not become great doctors.

-more-

Cost of the special program will be approximately $50,000 for the first year, Dr. Nelson estimates. (Tuition expenses, room and board, and other contingencies come to $4,845 per student for nine months of study.) By the time there are enough minority students in all five classes of the school, costs will jump to $400,000 annually.

"We are searching for funds to run the program," Dr. Nelson said. "Minority students admitted this year have all required financial assistance. For the first year, we are using reserve funds to make the program go. But foundations, which often in the past have been interested in sponsoring programs for minority students, have not been willing to fund them."

Many of the students this year were recruited by a special minority search committee. Dr. Jose Aguilar, committee chairman, traveled through the Southwest and arranged for several Mexican-American students to visit Stanford. Members of the Mexican-American Students Confederation assisted him in interviewing applicants from their minority group.

Another committee member, Paul Williams, a second-year medical student and member of the Black Students Union, talked with black applicants who visited the campus, and contacted and counseled by telephone those he could not meet personally.

In screening applicants other BSU members assisted, including Dr. Cyril Fabio, a dentist from East Palo Alto. Some applicants who visited Stanford took lodging at the homes of minority search committee members, allowing them to become personally acquainted with the candidates.

Finally, minority representatives ranked the applicants for recommendation of admission. Guidelines used by the search committee in its selections included:

. Evidence of academic achievement and promise of further attainment.

. Motivation for medicine.

. Consideration of how far the candidate had journeyed to reach a decision to apply to medical school.

. Evidence of humane concern for the existing problems in the student's minority group community.

Dr. Aguilar noted that as a result of publicity and recruitment efforts, 63 minority students applied for admission to the medical school this year. By contrast, during the previous year, when Stanford had no formal program, only 9 candidates applied.

"Minorities have not shown much interest in entering professional schools, because past promises have never amounted to anything," Dr. Aguilar said. "Our program for the first time spells out exactly what the opportunity consists of in terms of positions promised, and what the support will be.

"The fact that we have a program will undoubtedly have an impact on the educational system farther down the line. It will point out the inadequacies of education at the grade and high school levels and the failure to produce the talent medical schools require."

STANFORD--"Hunger, Poverty and Parasites in the U.S." will be the topic of a public lecture at 4 p.m. Monday (Oct. 20) in Room M106 of the Stanford University School of Medicine.

The lecture, sponsored by the department of community and preventive medicine, will feature Dr. Donald E. Gatch, a South Carolina country doctor who works among the poor in Beaufort County.

Dr. Gatch was among the first to point out that hunger was a daily fact of life among black families and to discover in South Carolina diseases related to malnutrition never thought to exist in developed countries.

After he charged publicly that he had seen children dying of starvation, that most black children in the area were infested with worms, and that families were living in hovels, he began losing his white patients. Every doctor in the county signed a statement deploring his "unsubstantiated allegations," and the local newspaper, the Beaufort Gazette, accused him of "running his mouth."

Ostracized by both colleagues and white patients, Dr. Gatch closed his office at Beaufort and moved to Bluffton to open a clinic for the poor.

Subsequently a survey, conducted by researchers from the University of South Carolina, the Meharry Medical College, and Vanderbilt University, substantiated Dr. Gatch's charges.

ADVANCE FOR A.M. RELEASE MONDAY, OCTOBER 13, 1969.

NOTE: Parents of Children with Neurological Defects will meet Tuesday evening October 14 at 7:30 p.m. in Room A335, the Pediatrics Conference Room, of Stanford University Medical Center. Speakers will be Mr. and Mrs. Arthur Tollkuhn of Parents and Friends of the Child Development Center, San Jose, who will talk about how their group united to work for a special cause.

STANFORD--The impersonal fact that a defective child could be born is easy to accept. But news that a child of yours has been born with a severe defect is a much more difficult matter to wrestle with.

In fact, the impact probably lasts for years. Learning to cope with the problems of defective children is not simple, nor is it automatic. But parents have found that they can learn from each other.

An example in the Mid-Peninsula is a group known as Parents of Children with Neurological Defects. Their children were born with myelomeningocele and in some cases hydrocephalus.

Organized around a core of parents whose children have been referred to the National Foundation March of Dimes Birth Defects Center at Stanford University Medical Center, the group welcomes new members and is eager to make itself available to Bay Area parents in the same situation. Their monthly meetings are usually held at Stanford.

Myelomeningocele is a condition in which the vertebral arches in the spinal column have failed to close during fetal development. There is an outpouching at some point along the spine, usually at the base of the spine, containing membranes and sometimes spinal cord tissue. Various children have varying degrees of motor and sensory impairment in the lower half of the body, including impairment of bowel and bladder functions.

In hydrocephalus, which is often associated with myelomeningocele, an abnormal amount of fluid builds up in the ventricles of the brain. Resultant pressure can enlarge the head and damage the brain. Fortunately, the defect can be corrected by a procedure known as shunting--a tube is inserted in the ventricles to drain the fluid elsewhere so that it can be circulated and eliminated.

Mr. and Mrs. Roger Cummings of San Jose were charter members when Parents of Children with Neurological Defects was started in 1968. By that time their son Russell was two years old and had already had operations for myelomeningocele and hydrocephalus.

They only wish the parents group had been in existence in 1966. "We wouldn't have felt so alone," says Roger Cummings.

"Now we have, and can help give, moral support," says Esther Cummings. "We know that others have faced similar situations and have lived through them. Also, it's encouraging to hear of any progress the other children make," she adds.

But the beginning was rugged. Right after Russell's birth the Cummings were told that there was no hope for the life of the child. Russell was not brought to his mother, and the Cummings were also told that he must be cared for 24 hours a day in the hospital. Further, they were informed that if he should survive, his mental abilities, as well as physical, would be minimal.

-more-

For the Cummings family, particularly for the mother, the news was almost devastating. Shaken, she returned home, where fortunately three older, lively sons awaited her.

The family authorized surgery for Russell when he was ten days old, but had no contact with him except that his father secretly went to visit him each day. Peering wistfully through the glass at his tiny son, Roger Cummings hoped the hopes of a parent, and wondered what was going to happen.

Suddenly one day when Russell was about a month old there was a change in the medical climate. Tests were performed. A doctor put in a call to Mrs. Cummings. Apparently, he said, the baby had a chance for healthy mental development.

Mrs. Cummings called her husband at work and together they literally ran to the hospital. They questioned the doctor for hours and hours--there were absolutely no guarantees. None at all. But they could take Russell home if they wanted him. They wanted him.

The mother saw and held her baby for the first time. And she was able to take him home to meet his brothers, Roger, now 13, Robert now 9, and Richard, who is now 7.

The ensuing years have been, as the Cummings knew they would be, a continuing uphill fight for Russell's well-being. Repeated surgeries and numerous visits to an array of pediatric specialists take a toll in time and emotion.

But Russell has responded well. And now, with their new friends in the parents group, they have a more positive sense of making progress.

"We don't get together to bleed," says Esther Cummings.

The parents meet to learn and to get to know one another.

The group has become a forum where family experiences can be shared, personal worries and fears can be expressed, and educational talks by various specialists can be presented. Topics on the programs have included orthopedic procedures and rehabilitation; neurosurgery; other corrective surgery; special schools, medical services and financial aid available to their children; and how to deal with urologic problems. There have also been purely social evenings.

The organization's success has also benefitted the doctors. "Through the group we are able to arrive at a far better understanding of what is bothering parents than we can when they visit the clinic," says pediatrician Dr. Luigi Luzzatti of the Birth Defects Center at Stanford. "And since clinic visits, in turn, offer very limited opportunities for educating parents, the talks presented at the group meetings are proving to be a valuable way of increasing understanding.

"As parental understanding increases, so does confidence and ability in handling the children," says Dr. Luzzatti.

As an example of one of the practical lessons the parents have learned in making the best use of time which must be spent with the special child in the family, Roger Cummings mentioned the exercises done for the child's legs. "We had been doing the exercising with a mind toward strengthening the muscles until we were enlightened that the real purpose is to prevent fixed contraction of the muscles," he said. "Just knowing this little fact prevents wasted time and useless expectations."

The best feature of Parents of Children with Neurological Defects is just being able to relax and talk with people who fully understand the problems, the Cummings agree. They welcome new members and would be happy to supply any information about the group. Mrs. Cummings can be reached by telephone at 258-6788, or by letter at 10180 Torrance Avenue, San Jose, 95127.

STANFORD--"It is time the teenager, our greatest natural resource, should receive the prime attention of the government and private philanthropy," a Stanford physician said last night.

"The pollution of our youth by drugs deserves as much attention as the problems of culturally disadvantage minorities," Dr. Stanford Rossiter told a class of science teachers and school administrators taking a new course on the problems of drug abuse at the Stanford University Medical Center.

Breaking teenage drug abusers into two groups, regular and occasional users, Dr. Rossiter, a clinical assistant professor of radiology at Stanford, noted that the regular users are a more complex or disturbed group of youngsters. "Herein are found psychotic and prepsychotic types, the emotionally disturbed, the inadequate personalities, criminal types and the rebellious kids and 'losers,'" he said. "Within this group are those who use any and every drug and these obviously are the ones most likely to have had experience with heroin.

"The losers, criminals and psychotics are very expensive to our society and drug abuse tends to enhance their socially undesirable qualities," the speaker pointed out. "Efforts to curtail their drug habits justify the full application of law enforcement against both users and sellers.

"The relatively large numbers of occasional users are an entirely different problem," Dr. Rossiter told the audience of 100 attending the lecture.

"These users are basically normal adolescents who use drugs for a variety of reasons, most of which involve a social experience in the sense of 'being where the action is' or being 'in'. Experimentation or satisfaction of natural curiosity motivates many of these teenagers.

"The principal harm in drug use by this group is not necessarily in the drug itself but in the constant perpetration of the illegal act of using the drug. This activity appears to deaden the social conscience, making other types of illegal conduct more readily conceivable," Dr. Rossiter stressed.

"The social organizations centering around drug abuse tend not to have the more customary social experiences of normal adolescent cultures. The attitudes toward police and other types of civil authority become hostile and the dangers of felony convictions may be taken lightly," he said.

"The full realization of damage to future opportunities and status resulting from criminal records has not been awakened in these youngsters," he continued.

A second problem with occasional drug use is the harm to performance in school, the speaker pointed out. "Grades drop, social contacts tend to wither and participation in school extracurricular programs is replaced by the subculture of drug abuse. A polarization develops that separates the users from others wham they may admire or respect initially, but whom they later come to envy, resent, or suspect as informers."

Speaking on the origin of drug abuse, Dr. Rossiter pointed out that the entire cultural and psychological environment of the teenagerhas undergone significant changes in one generation.

-more-

"The automobile permits a teenager to exist essentially aloof from parental or community supervision. Nearly every teenager has access to a car or to someone who does," he said.

"Leisure time is uncommitted and non-productive. Family unity has been severely strained by distractions such as television, working mothers, and replacement of home chores by automation and modern conveniences. Former sources of teenage recreation are drying up rapidly--the vacant lot to play in, places to ride a bicycle, uncrowded beaches or parks. The cost of most conventional ntertainments, such as movies, is becoming formidable.

"Because of the high cost and inaccessability of areas for legitimate entertainment, it is literally cheaper for teenagers to smoke pot together on a weekend than to take a date to a jazz festival or even to a drive-in movie ," Dr. Rossiter said.

"Information on chemicals and drugs, particularly those which affect mental behavior, has not been presented properly to children--nor for that matter even to adults. It is best that schools accept the responsibility of teaching what is good about these agents and wherein their dangers lie," he said.

"It should be obvious that education concerning the dangers of drug abuse and protection of the public against exploitation by criminal elements should be a prime objective of society.

"Legislation must be devised to control illegal drug traffic, to support research education, and to adjust our social structure to meet the problem of the teenager," Dr. Rossiter stressed.

"Teenagers themselves deserve support in their own efforts to salvage the dropouts, the social outcast, and the confused and frustrated drug users in their own subculture. Organizations such as teen drop-in centers are fully deserving of emergency funds to help them survive. Adult institutions should tuck these fledgling social creations under their protective wings and give them sanction as well as protection from undeserved criticism," he concluded.

Dr. Rossiter's lecture was the first in a series of nine being held weekly at Stanford. The course, sponsored by the Santa Clara Valley Science Teachers Association, is being presented as a public service by members of the Stanford faculty. Director of the program is Dr. Sumner Kalman, professor of pharmacology. Enrollment for the class is closed.

STANFORD -- Funeral services were held Tuesday in Palo Alto for Dr. Leo A. Sapirstein, an internationally known cardiovascular physiologist at Stanford University School of Medicine.

Dr. Sapirstein, professor of physiology in the Department of Radiology, died Sunday (November 16) at his home. He was 50.

Born in New York City October 6, 1919, Dr. Sapirstein was a product of New York public schools. He had an almost immeasurable IQ and entered City College at the age of 13.

At 17 he became a graduate student at the University of California, from which he received an M.A. degree in physiology in 1940. It was during this period that Dr. Sapirstein conducted his pioneering research in the role of the hormone renin on the circulation of the blood. His effectiveness both as a researcher and teacher led to his appointment as instructor in physiology at UC after he received his doctorate.

About the time he made his major contribution to the field of the physiology of the circulation of the blood, he began postgraduate work at UC. Following a period at the Public Health Corps, he received his Ph.D. in 1944. While continuing to pursue his scientific research, Dr. Sapirstein entered the University of California Medical School, receiving the M.D. in 1946.

He served on the faculty of the University of Southern California in 1950, and joined the faculty of Ohio State University in 1951 as associate professor, moving up through the ranks and becoming professor of physiology in 1955 at the age of 36. At Ohio State, his teaching and scientific efforts earned him the distinction of Man of the Year on three occasions, and his voluminous studies on the problems of regional blood flow and the mathematical methods for its analysis, won him international acclaim.

Dr. Sapirstein came to Stanford in 1961 as a visiting professor of physiology, becoming acting professor in 1963, and full professor in 1965, when he joined the research team in the Division of Diagnostic Radiology.

At his death he had contributed more than 80 papers to his field, and had completed a draft of a textbook of physiology.

He belonged to numerous learned societies and received many awards and distinctions for his work. He was particularly proud of a prize presented to him by Stanford medical students of the first-year class of 1963, for his ability "to present, organize, stimulate and challenge."

Apart from physiology, Dr. Sapirstein had an abiding interest in the beauty of the English language in which he was an accomplished stylist, parodist, and unpublished poet.

Dr. Sapirstein is survived by his two sons, Julian, 20, and Jonathan, 18, both Stanford students; his parents Mr. and Mrs. Simon Sapirstein of New York City; and a sister, Mrs. Rhoda Smith of Berkeley.

City Desks: Announcement of Dr. Glaser's new appointment is being made simultaneously in the Commonwealth Fund's New York office today.

Transmitted on Business Wire 11/19/69.

STANFORD -- Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school at Stanford University, has been elected vice-president of the Commonwealth Fund, the New York-based philanthropic foundation announced today.

Dr. Glaser will resign his Stanford post to join the Fund's staff September 1, 1970. He has been a member of the Fund's Board of Directors since May.

Expressing his personal regrets at the dean's decision, Stanford University President Kenneth Pitzer noted that Dr. Glaser had demonstrated outstanding leadership in dealing with the principal problems facing the medical school at the time he accepted the post in 1965.

These included the University's complex and lengthy negotiations for purchase of the City of Palo Alto's share in the Palo Alto-Stanford Hospital, the adoption of a new flexible medical curriculum, the creation of a program to increase minority enrollment, and the appointments of key faculty members.

"Under his leadership, the School of Medicine continued to advance its standing as a foremost center of research, educational innovation, and experimentation in health care," President Pitzer said.

For example, Stanford has initiated planning for a new hospital and ambulatory care center intended both to limit costs and improve patient care.

In announcing Dr. Glaser's appointment in New York, Quigg Newton, Commonwealth Fund president said: "Dr. Glaser brings to the Fund a background of exceptional leadership and accomplishment. His experience and insights, together with his imagination and energy, are certain to enhance the Fund's potential for dealing helpfully with the grave crisis confronting the country's health and medical enterprise."

-more-

The Fund is one of the country's principal foundations concerned with strengthening health opportunity in American life. Since its establishment in 1918, it has appropriated nearly $160 million for this purpose.

President Pitzer said he would consult appropriate groups immediately concerning the search for Dr. Glaser's successor.

He indicated he was appointing an administrative council to advise the vice-president for medical affairs and dean of the medical school for the remainder of his term, and to serve until a new dean is selected.

Administrative council members will be Dr. Robert A. Chase, professor and chairman, Department of Surgery; Dr. David Hamburg, professor and chairman, Department of Psychiatry; Dr. Halsted Holman, professor and chairman, Department of Medicine; and Nobel Laureate Dr. Joshua Lederberg, professor and chairman, Department of Genetics. Another faculty member being asked to serve is Dr. Paul Berg, professor and acting chairman, Department of Biochemistry, who is presently in Europe.

Dr. Glaser served as acting University president in summer and fall, 1968, and was praised by the Associated Students of Stanford University for his "outstanding administration" and for meeting student involvement "with human understanding, deep personal concern, and prompt action."

In 1968-69, Dr. Glaser served as president of the Association of American Medical Colleges, and is a member of the Board of Medicine of the National Academy of Sciences. Most recently, he was appointed to the Task Force on Science Policy, established by President Nixon, to prepare recommendations for the future development of the federal government's role in science affairs.

Dr. Glaser, 51, was educated in the public schools of St. Louis and University City, Missouri. He received his A.B. degree at Harvard in 1940, and his M.D. magna cum laude there in 1943.

After serving his internship and residency at the Barnes Hospital and the Peter Bent Brigham Hospital, he rose steadily through the ranks at Washington University in St. Louis where he served as associate dean of the Medical School from 1955 to 1957.

He then moved to the University of Colorado as dean of the School of Medicine, becoming vice-president for medical affairs before moving to Boston to become President of the Affiliated Hospitals Center and professor of social medicine at Harvard Medical School.

He is married to the former Helen L. Hofsommer, M.D. They have three children: Sally Louise (born 9/5/50), Joseph II (1/22/52), and Robert Joy, Jr. (8/1/53).

Mailed November 19, 1969.

STANFORD -- The Stanford University Medical Center Auxiliary has voted to donate $25,000 to Stanford University Hospital for the building of plastic and reconstructive surgery suites at the Hospital's Hoover Pavilion.

Auxiliary president, Mrs. George E. Boyd of Los Altos Hills, announced the gift today, saying that the volunteer organization intends to make two additional gifts of $25,000 or more for the project in 1970 and 1971.

Expressing appreciation, hospital director Dr. Thomas A. Gonda said "We are deeply indebted to the Medical Center Auxiliary for this gift which will enable us to again use Hoover Pavilion as a surgical unit of the hospital.

"The Hoover Pavilion is well suited to care for patients who need short term acute admissions for procedures that do not require general anesthesia. A number of these patients are orthopedic and burn patients, so we also plan to develop extensive physical and occupational therapy facilities there to provide excellent rehabilitation care," he said.

The plastic and reconstructive surgery suites at Hoover will include related facilities such as nursing stations and on-call quarters for a plastic surgeon and a general house doctor.

The Auxiliary has served the Medical Center since the Center opened in 1959. It raises its money solely through the gift shops it operates and staffs at the hospital.

STANFORD--Children who are scheduled to be patients at Stanford University Hospital can now take a pre-admission tour if they wish.

The tour, given each Sunday afternoon at 1 o'clock, is planned as a familiarization experience for pediatric patients and also their parents so that the Hospital won't seem such a strange place when the child is actually admitted and medical procedures begin.

"We're doing this to help the child conquer his fears about being hospitalized," says pediatric nursing supervisor Joyce Smith. "The hospital represents a complete unknown to him. When he enters he will be concerned about being separated from his parents. If he is placed in a totally new environment, it may add to the tension. But by bringing him here in advance we can show him what to expect."

Among the things the children see on their tour: hospital beds, buzzers which summon the nurse to the bedside, Identaband bracelets, and other children. The prospective patients are intrigued to find other children romping around a playroom where there is a life-size doll house. Games and crafts go on in the playroom, and movies are shown there on certain evenings.

On the tour, the pediatric nurse explains that each child may bring his own pajamas or sleep in some belonging to the Hospital. She does definitely suggest bringing slippers and a robe. A favorite toy is fine, too.

The child is told that a number of people will be concerned about his welfare during the stay in the hospital -- doctors, nurses wearing gaily colored aprons, girls in candy-striped dresses who are about as old as the family babysitter, a recreation director, and for bigger children, a schoolteacher. It's a long list, too long to remember, but the lasting impression for the child is that he will not be left alone.

In fact, he learns, his mother and father may come and see him anytime, because at Stanford University Hospital, visiting hours in the pediatrics ward are unlimited. This policy reassures parents as much as it does children.

The pre-admission tours are a help to the nurses, too. "By getting a chance to talk with each child we learn something about him as an individual, and are that much better prepared to help him adjust when he arrives," comments Miss Smith.

The invitation to the tour is included in the pre-admission information packet sent out by the Hospital.

EDITORS: On Thursday, November 6, 1969, we have arranged a press conference with Dr. Robert H. Dreisbach to announce the results of his study of the environment of the San Francisco Bay Area Region. The study is believed to be one of the most detailed reports of human ecology of the region ever put together, and it is Dr. Dreisbach's hope that it may assist local communities in their future course and planning. A major part of the 576-page report, titled "Handbook of the San Francisco Region," relates to the quality of the air we breathe, which is within the area of the author's competence as a toxicologist and professor of pharmacology at the School of Medicine. But the report also contains many innovative ideas about planning, taxation, and related areas. The solution to the Bay Area's regional problems may lie in what Dr. Dreisbach regards as "obvious, but apparently unthinkable answers." Several stories, based on the report are enclosed in advance, and we are hopeful that advance copies in galley form will be available at the conference. The press conference will be at 9:30 a.m. in Room W001, adjacent to the News Bureau, in the Stanford University Medical Center. Please notify us if you plan to attend.

Editors: This is the first of a series of seven articles dealing with the deterioration of the environment of the San Francisco Bay Area. The articles are based on a forthcoming book on the ecology of the Bay Region by Stanford University pharmacology professor, Dr. Robert H. Dreisbach. The articles have been prepared by the Stanford Medical Center News Bureau, in cooperation with the author. A press conference has been scheduled with Dr. Dreisbach on Thursday, November 6 at 9:30 a.m. in Room W001, adjacent to the News Bureau in the Medical Center. Please notify the New Bureau if you plan to attend.

(ADVANCE) FOR PM RELEASE THURSDAY, NOVEMBER 6, 1969

STANFORD-- A grim warning that the San Francisco Bay Area Region either start to clean up its precious environment or face burial under its own garbage was sounded today by a Stanford University pharmacologist.

Dr. Robert H. Dreisbach, professor of pharmacology at the Stanford University School of Medicine, said:

"The San Francisco Bay Region serves as a prime example of ecological imbalance. It is increasing its population and, at the same time, is unwilling to pay the price to control sewage and garbage disposal, air pollution, crime, and traffic congestion.

"If man continues to exist without destroying himself in the next century, future generations will look upon us as ecological primitives.

"We sneer at stone-age man, considering him primitive and not worth our attention. At least he was in equilibrium with his environment. If man is to survive, the essential key is equilibrium."

The Stanford professor who specializes in toxicology made his remarks in a 576-page ecological report, titled "Handbook of the San Francisco Region," to be published November 17.

"San Francisco, queen of the cities, is equal to the rest of the Bay Region communities in ecological idiocy," Dr. Dreisbach wrote.

He explained that the city is piling office buildings and apartments higher and higher in a desperate attempt to get into balance with expenses. At the same time, the city is unwilling to pay the price for its sewage disposal, and dumps garbage in the Bay, where all who pass may see.

Dr. Dreisbach added:

"We think that the ocean will tolerate our wastes, proposing to dump inadequately treated sewage and compressed garbage miles at sea without thought to ecological consequences.

"At the same time we think the ocean will be able to feed untold billions of people. We make this contention in the face of declining production of fish from pesticide contamination."

Dr. Dreisbach blames the destruction of the Bay Area environment to these factors:

- The automobile has made possible the widespread subdivision of agricultural land. Some cities even advertise with pride that they still have agricultural land to subdivide.
- Developers and builders want to profit from inexpensive agricultural land.

-more-

. City administrators want to get as much tax income as possible.

. Lax home building regulations allow cheap construction.

. Rapid population growth in the remainder of the country supplies a mobile population to move to the Bay Area.

The idea of an ever-expanding tax base, so enthusiastically supported by most local governments, is a myth, the pharmacologist said.

"Why should we be trying desperately to fill open space? Open space has no inherent cost of operation. It does not need sewers, classrooms, administration buildings, police," Dr. Dreisbach said.

He cited the city by the Golden Gate as an example of the tax myth.

"San Francisco has more jobs than residents but is still unable to pay the cost of its operation and must tax commuters," he said. "They must build higher and higher office buildings in a never-ending spiral of increasing costs as population density rises."

To halt the destruction of the Bay Area, Dr. Dreisbach recommended what he regards as "obvious, but apparently unthinkable, answers."

First, the Bay Area Region must control its growth rate.

Second, it must ban the individual automobile and develop mass transportation.

"The need of cities for more tax revenue forces them to convert all open land to houses and industry," he said. "However, cities fail to consider that costs of government do not stem from open space but from people and their needs."

He said one approach to discourage cities from expanding is to put all tax money into a common statewide pool that would be redistributed to cities according to population.

"Communities would seek to stay small since costs per person go up in relation to population density," Dr. Dreisbach explained. "Cities would be relieved of the pressure to subdivide open space, and the distribution of tax wealth would be equalized."

He suggested that remaining open space and agricultural land in the Bay Area be freed from taxation or purchased. Public ownership would allow planning and development of the land in a manner that is compatible with the needs of Bay Region communities.

Dr. Dreisbach said that outright purchase of desirable land for parks and agriculture might cost $3 to $10 billion. The money might come by taxing affluence and those things that have the most destructive effect on the environment.

One of these is the automobile, which accounts for more than half of the air pollution of the Bay Area.

"The cost of the automobile to the individual and to society is totally unjustified in relation to the benefits derived," Dr. Dreisbach commented. "The enormous amount of money and effort now going into the automobile could begin to search for solutions to many of the pressing problems of our cities.

"The automobile has always been sacrosanct, like the sacred cows of India, but is there a valid reason for the sanctity? Its main justification is an economic crutch because we are unable to create a stable economy in any other way. -more-

"The automobile is the single most destructive element to living quality, and as such it should be taxed."

He said the damage caused by the automobile to society, including its use of a disproportionate share of the world's resources, could justify taxation of at least 50 cents per mile. A tax of 10 to 20 cents per mile would be an appropriate beginning.

The Stanford pharmacologist added that with increasing taxation of the automobile, public transportation would come into demand, and this could be supplied at not less than cost.

Turning to the issue of waste disposal, Dr. Dreisbach said that in 1960 the nine Bay Area counties generated 2,607,000 tons of refuse. Estimated at about 4 pounds per person a day, the same cities today dump 4,560,000 tons of garbage into the Bay annually. This would be enough to build a wall 36 feet wide by 30 feet high from San Francisco to San Jose.

"The harmful effects of disposing wastes by covering them under layers of dirt include reduction of the Bay and consequently reduction in tidal currents and oxygenation of water," he said. Continued filling, coupled with excessive escape of organic matter, would suffocate fish and other wildlife."

Reduction of the Bay would increase the likelihood of temperature inversions. This in turn would increase the concentration of pollutants, which may reach that of Los Angeles, he said.

An alternative to filling the Bay, Dr. Dreisbach said, would be to collect wet garbage and sewage solids at the source, treat them to make them bacteriologically safe and odorless, and use them for agriculture.

Cans could be recovered for their metal content, and paper could be used almost indefinitely, he added. As for disposable items, he urged that they be banned altogether.

(Tomorrow: California marine life being studied to death.)

(ADVANCE) FOR PM RELEASE THURSDAY, NOVEMBER 6, 1969

STANFORD--Marine life which thrives in the tide pools along California's 1,200-mile coast line is in danger of being studied to death, a Stanford University pharmacologist reports.

"Increasing numbers of tourists and students, laden with buckets, jars, and plastic bags, are swarming over state beaches by the thousands, collecting anything and everything in sight," writes Dr. Robert H. Dreisbach, professor of pharmacology at the Stanford University School of Medicine.

His comments appear in an ecological report about the San Francisco Bay Region to be published this month.

Dr. Dreisbach said that flights by state aircraft have observed 59 buses on one day, parked at access areas from Tomales Bay to Natural Bridges State Park, and large groups of collectors. On another beach as many as 400 children were observed collecting at one time.

On a single day at Moss Beach in San Mateo County, a warden counted 12 busloads of students collecting specimens. Three days later, another 12 busloads of students arrived.

Another warden reported 30 schoolbuses in the Duxberry-Agate Beach of Marin County on a single day. All the children were collecting marine specimens.

In Santa Cruz County nearly 7,000 visits of collectors annually have been recorded by wardens in the Elkhorn Slough area. The collectors are students from five state colleges.

There is clear evidence that uncontrolled collecting of marine specimens is common throughout the California coast, Dr. Dreisbach said.

Collecting is poorly supervised by parents and teachers, he said. Students turn every loose rock in the area and leave it upside down, with little or no regard for the welfare of the marine organisms. Some students pick up more specimens than they need, and dump them in the parking lots before they leave.

"The result of such activity is that starfish, gastropods, limpets, and chitons are becoming scarce," Dr. Dreisbach said.

He added:

"The waste of marine life by unthinking persons is deplorable. And even the legitimate uses of collecting for scientific and educational purposes can seriously deplete marine life species in tide pools, if the activity is not regulated."

Dr. Dreisbach said that threatened depletion of marine life at Bodega, Tomales and Bolinas, prompted the director of the Pacific Marine Station at Dillon's Beach to develop a study program in marine environment for teachers and students.

He said that possible steps to prevent extinction of marine life should include establishment of marine reserves where collecting would be prohibited, enabling legislation that would give a state agency authority to regulate collecting (at present no single agency is responsible), and programs to train teachers in proper collecting philosophy and techniques.

(Tomorrow: Smog is worse than people realize.)

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310
EDITORS: This is the third of seven articles on the quality of the environment of the San Francisco Bay Region and what must be done to avert its deterioration from continued pollution.
FOR PM RELEASE THURSDAY, NOVEMBER 6, 1969

(ADVANCE) STANFORD - People would be appalled if they knew how their welfare is being trifled with because of failure of San Francisco Bay Area cities to come to grips with air pollution, a Stanford University pharmacologist contends.

"We are conscious of air pollutants only when they restrict visibility," comments Dr. Robert H. Dreisbach, professor of pharmacology at the Stanford University School of Medicine, in his new book, "Handbook of the San Francisco Region."

However, only 210 tons or 2 percent of the 10,215 tons of injurious pollutants emitted daily are visibility limiting," he writes. One of these is ozone which is not emitted as such, but is generated by the action of light and other pollutants and oxygen, he said. Colorless, gaseous pollutants, such as carbon monoxide, ozone, and hydrocarbons and other organic compounds are as transparent to visible light as the normal constituents of air.

Only nitrogen dioxide absorbs in the visible range of light and contributes a brown color to the atmosphere, he explained. "If all pollutants were as visibility limiting as the particulate matters, our range of vision would be limited to only a few hundred feet instead of a mile or two during our worst air pollution episodes," Dr. Dreisbach said.

He questioned the validity of standards for air quality proposed for adoption by the California Air Resources Board last June. The standards prescribe the levels of air pollutants which humans can inhale without danger to health.

There is no evidence to indicate that these standards are completely harmless," Dr. Dreisbach said. "The levels are determined, in part, by the possibility of being (technologically) able to control emissions in the foreseeable future. At present, recommendations for oxidant, nitrogen, and dioxide visibility are frequently exceeded," he added.

The Stanford pharmacologist called for a series of bold experiments to determine the source of air pollution that would indicate the guilty unequivocally. The experiments would be run every second weekend. First, every possible source of air pollution would be shut down--automobiles, trucks, buses, aircraft, ships, trains, factories, backyard and agricultural burning. On succeeding weekends, polluters would be permitted to operate in succession--buses, trucks, aircraft, trains, industry, agricultural burning, automobiles and so forth.

The series would be repeated often to obtain convincing data. During each experiment, visual range would be monitored carefully, along with other measurements of air pollution already being taken by the Bay Area Air Pollution Control District. Dr. Dreisbach acknowledges that the cost of such an experiment would be high, but he feels it is more than justified.

He said that the Los Angeles Air Pollution Control District has instituted a program that now excuses some two million students through high schools from strenuous activities on days of high smog readings.

He added: "How long before the same happens in the San Francisco Region? Do we really care more for polluters than we do for our children?" (Tomorrow: Automobile vs environment--is the cost justified?)

(ADVANCE) FOR PM RELEASE THURSDAY, NOVEMBER 6, 1969

STANFORD -- Have you ever kept track of how much it costs to own a car?

A Stanford University pharmacologist has figured it out. He contends that your investment, at the end of two years, to own and operate an automobile, is exactly $7,273.

If you didn't buy a car, but instead chose to put the money into savings, your account would have added up to $204,119 in 45 years, he said.

Here is how Dr. Robert H. Dreisbach, professor of pharmacology at Stanford University School of Medicine, arrived at this figure for a station wagon with some extras:

Price with taxes and license is	$ 4,000	
The first year of expenses are:		
gasoline: 1,000 gallons x 36.9 cents	369	
garage rent	600	
lubrication	100	
insurance	150	
parking and bridge tolls	50	
interest on investment	263	
Total investment at end of first year		$ 5,532
The second year of operating costs are	1,269	
new tires	125	
interest	347	
Total investment at end of second year		$ 7,273

The Stanford pharmacologist calculated that a monthly saving of $100 at 5.25 per cent interest, compounded daily, would add up to $204,119 in 45 years if all interest were retained.

Dr. Dreisbach, author of a new book on the ecology of the San Francisco Bay Region, used the figures to prove his contention that the cost of the automobile to the individual and to society is totally unjustified in relation to its benefits.

He estimated that Highway 101, in Palo Alto, carried 4,761 automobiles and 5,614 passengers in three northbound lanes during peak traffic in one morning.

If these automobiles had been buses, he said, they could have carried 230,000 passengers.

The cost of transportation is determined by load factor and time. Of all available modes of transportation the bus has the lowest operating cost, he added.

Dr. Dreisbach said that the enormous amount of space now needed for transportation is made necessary by total reliance on individual automobiles. (He rides a bike to work each day.) (more)

In the last nine years, the amount of space taken over by automotive transportation in the Bay Area amounts to 15 square miles. "How long will it take to turn the area into an asphalt desert?" he asked.

"Automotive transportation is so destructive to general living quality that a 10-year moratorium on further road construction would be justified to study ways to make the 10 billion square feet already paved more effective," Dr. Dreisbach said.

"The tangible costs of operating an automobile (highways, fuel, traffic control, accidents, insurance, court expenses) amount to more than 50 cents per mile," he said. "To this must be added the intangible costs which cannot be easily measured--air pollution, sound pollution, water runoff from streets and highways, crime, and the impairment of mental health which often occurs when freeways are built with no consideration for nearby residents."

Dr. Dreisbach gave an example of what he regards as one of the little considered costs of automotive transportation--oil spillage.

"If one looks during a rainstorm the streets are dotted with patches of irridescent colors indicating oil spills," he said. "These are carried on the wet surface to gutters which carry a noticeable film of oil to storm drains and end up on the surface of the Bay.

"If each vehicle spills one pint of oil per year, this can contribute 20 drops per day and a total of 1,400 tons of oil annually for all vehicles in the Bay Region.

"Since each milligram of oil will cover 10 square feet of water surface, the amount spilled daily is more than enough to cover the entire Bay with a film of oil."

When it is not raining, the oil mixes with dust on the street and is repeatedly ground by the passage of cars until some of the particles become small enough to be dispersed into the air we breathe.

"Run your finger over an exposed surface. Part of the black oily deposit comes from spilled oil," Dr. Dreisbach said.

The answer to the problem, both in terms of air pollution and safety, is the development of mass public transportation in the Bay Area Region, the pharmacologist said.

To bring about a demand for public transportation, Dr. Dreisbach recommended taxing the individual automobile out of existence.

"If other forms of consumption, such as land ownership and nonfood purchases are taxed, why not taxation of the automobile in some reasonable relationship to its injurious effect on the environment?" he asked.

(Tomorrow: Fill may destroy Bay's natural air conditioning.)

###

News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

Editors: This is the fifth of seven articles on the quality of the environment of the Bay Area Region.

(ADVANCE) FOR PM RELEASE THURSDAY, NOVEMBER 6, 1969

STANFORD -- Smog levels in the San Francisco Bay Area may reach those of Los Angeles if Bay filling is allowed to continue, a Stanford University pharmacologist predicts.

Dr. Robert H. Dreisbach, professor of pharmacology at Stanford University School of Medicine explained:

"The mild climate of the San Francisco Bay Area is not wholly an unmixed blessing.

"The domination of the semipermanent high pressure over the eastern Pacific Ocean that causes rainless summers and infrequent winter precipitation is also responsible for a stable stratification of the air which makes the region prone to air contamination.

"The condition of warm, dry air, riding above cool marine air, persists along the California coast during almost the entire summer and during some periods in the winter.

"A temperature inversion caps the marine air over the San Francisco Bay Area during practically of the summer and about 15 per cent of the time in winter. The practical result is that the volume of air into which contaminants can be dispersed is severely limited."

Dr. Dreisbach made his analysis of weather conditions in his "Handbook of the San Francisco Region," a compendium of the ecology of the region being published this month.

He said temperature inversions in the Bay Region also occur from other causes which complicate the smog picture. On clear nights with low humidity, the earth's surface loses heat rapidly. The energy loss is especially large during the winter.

As the ground cools, the air in contact also cools, producing a temperature inversion in the atmosphere, Dr. Dreisbach explained. Depending on the wind speed, the base of this "radiation inversion" can be located at the ground or several hundred feet above. Once formed, it behaves like any other inversion as far as its effect on capping the air below is concerned.

"Radiation inversions occur more frequently over land than over water," the pharmacologist said. "The filling of the Bay can increase the incidence and intensity of radiation inversions. This in turn will increase the concentration of pollutants.

"With the additional emission of pollutants from expansion onto a filled Bay, the frequency of occasions with dangerously high concentration of pollutants may reach that of the Los Angeles area."

Editors: This is the sixth of seven articles on the deterioration of the environment of the San Francisco Bay Region.

(ADVANCE) FOR RELEASE THURSDAY, NOVEMBER 6, 1969

STANFORD -- "One of our most precious assets is agricultural land, yet land is fast disappearing in the San Francisco Bay Region, with disastrous effects for the future."

This is the opinion of Dr. Robert H. Dreisbach, professor of pharmacology at the Stanford University School of Medicine.

In his study of the Bay Region to be published this month, Dr. Dreisbach contends that the disappearance of agricultural land in Santa Clara County has had an effect on food import markets abroad.

Although the effect was barely visible, the pharmacologist believes it was a warning of worse things to come, if valuable agricultural land continues to be diverted to other uses.

In 1945 Santa Clara County raised 31 per cent of the apricots in the state, according to Dr. Dreisbach, but in 1964 the fraction had fallen to 24 per cent.

In 1940, Santa Clara raised 32 per cent of the total state crop of plums and prunes, but in 1964 this fraction had fallen to 21 per cent.

"This change was even noticeable in Europe," Dr. Dreisbach said. "In 1960, dried apricots were imported to several European countries from Santa Clara County. By 1964 these were not available."

In another example, San Mateo County raised quantities of row crops both near the Bay and near the ocean. Now these lands have been converted almost entirely to houses, and the remaining agricultural land is being subdivided rapidly.

"One would think that agricultural land would be protected above all to prolong the day when food will be in short supply, Dr. Dreisbach commented.

If this is not done, we must expect that the first foods to disappear in the chain leading to shortage would be the variety fruits and exotic vegetables, he said.

"Apricots and artichokes that grow only in restricted areas are fast disappearing from the market," Dr. Dreisbach explained, adding that this is another reason why these special lands must be preserved for the future.

Outright purchase of the desirable land by public agencies to guarantee retention for agriculture might cost $3 to $10 billion, but the pharmacologist believes the need for this land would justify such action, and communities could probably afford it.

The remaining agricultural and forest land still open in the 10 counties of the Bay Area amounts to less than half of an area of 4.7 million acres.

-more-

"People in these counties spend one-half billion dollars annually on malt liquor, cigarettes, soft drinks, coffee and toiletries. They spend another $3 billion on automobiles," he said.

If the land were acquired by public agencies, Dr. Dreisbach said, much of the cost would be recovered by long-term lease rights for agriculture, not excluding, of course, the home building and limited industrial development that would be compatible with the needs of recreation.

Dr. Dreisbach believes that the money for such land purchase could come from taxing affluence, and taxing those things that have the most destructive effect on the environment of the region--pavement, garbage, and pollution.

He also suggests that taxes be removed from land which is agriculturally productive.

Unless we take these bold steps, Dr. Dreisbach believes, "we will never be able to return our land to agricultural production when population pressures cause food shortages."

"In Europe," he said, "diversion of food-producing land has not been possible because all food is needed for consumption or export."

(Tomorrow: Bay's recreation potential only slightly realized.)

EDITORS: This is the last of seven articles dealing with the destruction of the environment of the San Francisco Bay Area Region.

FOR PM RELEASE THURSDAY, NOVEMBER 6, 1969

(ADVANCE) STANFORD - The San Francisco Bay has enormous recreation potential so far only slightly realized.

Water temperature, south of Coyote Point, is above 70 degrees for three months in summer, and south of Dumbarton Bridge, the water temperature reaches 75 degrees for part of the time, reports Dr. Robert H. Dreisbach of the Stanford University School of Medicine. He said:

"Yet, water-contact sports in this warmest part of the Bay are denied the public for health reasons."

He added that if ways were found to clean the polluted water, swimming and other forms of recreation would become one of the best things the Bay Region could offer. This, however, is not the case because all evidence shows that the Bay's water quality is not getting better.

"Boating on the Bay is minimal," Dr. Dreisbach said. "No attention has been given to finding ways to provide boating without requiring ownership. Almost the only public facilities on the Bay are marinas to satisfy the need to store privately-owned boats that are used, at most, a few hours a week.

"Emphasis on private ownership bars a large segment of the population from this enjoyable recreation."

Dr. Dreisbach is professor of pharmacology in the Medical School. His remarks appear in a 576-page report of the ecology of the area being published in November.

The shoreline of the Bay Region is 276 miles long. Yet, only five miles of Bay shoreline are actually open to the public, Dr. Dreisbach said.

He continued: "In 1850, the total area of the Bay system to the confluence of Sacramento and San Joaquin rivers was nearly 700 square miles. Of these, 568 square miles were shallow enough to fill. Up to 1958, 243 square miles had been filled or diked, leaving only 78 square miles of marsh.

"Since that time, filling has continued at about four square miles per year, and the water surface is now estimated at 435 square miles. Filling and diking has reduced the surface area oxygenating capacity by 40 percent and the tidal exchange by about 100,000 acre feet.

"Once abundant sea otters have been exterminated.

"A shell-fish industry, formerly worth over $1 million annually, has been wiped out.

"Erosion silt enters the Bay at a rate of eight million tons per year, requiring an estimated 8.5 million tons of dredging annually, much of which is redeposited elsewhere on the Bay shoreline.

"Solid wastes, most of which are used as Bay fill, are deposited at a rate of 4.5 million tons annually.

"At least one billion gallons per day of industrial and domestic wastes are discharged into the Bay."

Dr. Dreisbach noted that the deterioration of the Bay Area Region environment shows that the answers cannot be left to single city councils, or board of supervisors. It will require the utmost involvement of informed citizens to arrive at the most beneficial solutions.

STANFORD--Stanford University heart transplant patients can now monitor their own hearts for signs of rejection.

Each of the five patients who has been discharged from the hospital to resume normal living, wears a small portable tape recorder for a period of 10 hours, two days a month. Leading into the recorder, which hangs at the patient's side from a neck strap, are three electrode wires that are taped to the patient's chest and provide a continuous, 10-hour electrocardiogram (EKG) recording for evaluation by Stanford physicians.

"With the data provided by the EKG recording over a substantial period of time, our ability to study the overall function of transplanted hearts and to detect heart arrhythmia, or an irregular heart beat, is greatly increased," said Dr. David Clark, a cardiologist on the Stanford heart transplant team. "The presence of arrhythmias may be an indicator of chronic rejection."

Previously, the patients' heart function was monitored only for a brief period of several minutes during their weekly or bi-weekly visits to the Stanford University Clinics.

"The chance of detecting an arrhythmia during this time was quite slim," Dr. Clark said. "Now we can get continuous EKG readings during periods of varying physical activity and sleep and can take steps if necessary to combat the rejection process in its earliest stages.

"To date our success in diagnosis and treatment of rejection has been very encouraging. This additional tool will further our capability to cope with this problem."

Chronic rejection, Dr. Clark explained, appears to take place slowly over a long period of time. It results in an accumulation of tissue deposits on the walls of arteries in the heart. If severe, this accumulation can eventually cut off the blood supply to the conduction center, or natural pacemaker, of the heart.

"The heart's own pacemaker is a small mass of specialized cells in the upper right chamber of the heart which initiates the electrical impulses that cause the heart to contract," Dr. Clark said. "When the blood supply to this area is insufficient because of gradual blockage of the artery, the heart may beat irregularly.

"This condition can be relieved by implantation of a man-made, battery-operated pacemaker which will control the beating of the heart by releasing a series of rhythmic electrical discharges whenever the heart rate slows," he pointed out.

The decision as to when or if to use a pacemaker is made by the physicians after review of the EKG data. Special equipment converts the tape to electrical impulses which are shown on a TV-like screen. All 10 hours of recorded information can be viewed in 10 minutes, and if an irregularity is detected, a stop-action device permits close scrutiny of the arrhythmia.

The recorder and screening equipment have been loaned to Stanford temporarily by the Palo Alto Medical Clinic.

STANFORD -- Bobbette K. Ranney, a fifth year student at Stanford University School of Medicine, is this year's Stanford recipient of the Pfizer Laboratories Medical Scholarship.

The scholarship, in the amount of $1,000, was awarded on the basis of Miss Ranney's outstanding scholastic record. She has been commended on fourteen separate occasions for honors performance in medical school.

The daughter of Mr. and Mrs. Robert C. Ranney, Jr. of Kirkwood, Missouri, Miss Ranney plans to take her internship training in pediatrics.

Pfizer Laboratories makes scholarship awards at all the medical schools in the United States.

Editors: The following story released jointly by Stanford University School of Medicine and the NASA-Ames Public Affairs Office. Photographs of Mrs. Phillips have been supplied to San Francisco wire service offices.

ADVANCE FOR RELEASE FRIDAY, DECEMBER 26, 1969.

STANFORD-- A young woman in Sunnyvale, Calif. is alive and active this holiday season all because she spent 10 hours in a pressure suit made for test pilots.

The life of Mrs. Mary Phillips, 25, was saved by the efforts of a team of doctors and researchers from the Stanford University Hospital and the National Aeronautics and Space Administration.

The NASA-Ames Research Center, Mt. View, Calif, reacted quickly when the hospital's chief resident surgeon explained the critical condition of Mrs. Phillips, whose internal bleeding could not be halted by established procedures. The pressure suit, or G-Suit, did the trick.

Doctors reported today that the pressure suit procedure, which took place last Sept. 23, appears to have been a complete success. Examination shows no further bleeding, and the patient has resumed her normal activity.

Prior to application of the pilot's G-Suit, Mrs. Phillips had undergone nine operative procedures. All had failed to stop the difficult abdominal hemorrhaging. She had received 46 pints of whole blood and 64 units of plasma in a five-week period.

The G-Suit is worn by pilots to avoid blacking out during high-speed maneuvers. It applies pressure to counter draining of the blood from the brain and upper body. Such a suit was provided by researchers from the Biotechnology Division of the National Aeronautics and Space Administration's Ames Research Center, Mountain View, Calif. Ames is now studying further medical applications of pressure suits.

Fitted to Mrs. Phillips at Stanford University Hospital, the G-Suit arrested abdominal bleeding overnight, during the ten hours in which it was applied.

The patient had entered the hospital to undergo a minor operation. Surgical exploration to determine the cause of bleeding following this initial surgery showed an apparent slow oozing of blood within the pelvic area, but with no evidence of active arterial bleeding.

Subsequent attempts to control this diffuse bleeding included pelvic packing, hypograstric artery ligation (tying off arteries supplying blood to the area of bleeding), and other surgery.

Following these measures, the patient was transferred to Stanford Hospital where Dr. Robert Mason, Assistant Professor of Surgery, recalled a reference in the surgical literature to blood-flow stoppage by a pressure garment. This idea grew out of early brain surgery work and research by Dr. W. James Gardner of the Cleveland Clinic, Ohio.

-more-

Dr. H. Ward Trueblood, Chief Resident in Surgery at the hospital, then telephoned Ames researchers Dr. Alan Chambers, Hubert Vykukal, and Richard Gallant. He outlined to them the seriousness of the patient's growing hematoma (blood clot) and the failure of all known methods to stop the bleeding.

The Ames group studied the problem and decided a G-Suit could provide the kind of pressure required. Within three and a half hours, they had modified the suit and delivered it to the hospital where it was put on Mrs. Phillips immediately. NASA people had provided the suit with new hoses, couplers, and two pressure regulators to allow a range of pressures, and inflation of the suit by the hospital's gas pressure cylinders.

According to Dr. Ralph Pelligra, Chief of the Medical Services Branch of the Ames' Simulation Sciences Division, the suit apparently reduced the difference in pressure between the blood within the arteries and the tissue outside them. This relatively small reduction of pressure difference apparently was sufficient to allow the blood to coagulate in the normal way.

Dr. Pelligra is studying applications of the pressure suit technique to other clinical problems.

A G-Suit is an adjustable nylon garment containing inflatable layers, located around the pelvic, abdominal, and leg areas. The suit was inflated to a pressure of 30 mm of mercury for ten hours. This is about a quarter of normal blood pressure for most people.

BULLETIN #2 Kulhanek, Dr. Leslie

Room C003
(415) 321-5310

December 20, 1969 11:00 a.m.

Dr. Leslie James Kulhanek, 29, who was shot and seriously wounded by an unknown assailant in the Stanford University School of Medicine student lounge Friday night, died this morning at Stanford University Hospital.

Dr. Kulhanek of 225 Wilton Avenue, Palo Alto, a first-year resident in medicine, and his wife Janet, were attending a Christmas party, given annually by the Department of Medicine, when the shooting took place at 8:15 p.m.

Witnesses at the party reported that the assailant approached the victim, and after what appeared to be a brief verbal exchange, fired three shots at Dr. Kulhanek's chest, and then fled.

Dr. Kulhanek was given artificial respiration and taken to surgery where an attempt was made by a team of surgeons to repair tears caused by the bullets in the great vessels of the heart.

Immediately after the incident, more than 100 faculty members, medical school and hospital personnel responded to a call for type 0 blood at the center's blood bank. Forty-five pints of blood were used. The surgery was completed at 2:30 a.m.

Palo Alto police are investigating the incident, and are reported to have a suspect in custody.

Dr. Kulhanek was described by his professors and associates as one of the outstanding medical residents this year. He was a graduate of the University of Colorado Medical School. He came to Stanford for internship training in 1968. In addition to his wife, he is survived by his parents, Mr. and Mrs. Leslie Kulhanek of 5511 Pine, Boulder, Colorado.

An autopsy is being conducted by the Santa Clara County Coroner's Office. Funeral arrangements are pending.

Bulletin/ December 19, 1969

A 29-year-Old resident physician was shot and seriously wounded by an unknown assailant at Stanford University School of Medicine student lounge Friday night.

The victim was identified as Dr. Leslie Kulhanek of Palo Alto. Dr. Kulhanek and his wife were attending a Christmas party, given annually by the Department of Medicine, when the incident took place.

Participants at the party reported that the assailant entered the lounge, and after what appeared to be a brief verbal exchange, fired three shots at Dr. Kulhanek, and then fled.

Dr. Kulhanek was given artificial respiration and taken to emergency room, and then surgery where an attempt is being made to remove the bullets.

Immediately after the incident, many faculty members, and hospital employees responded to a call for blood at the center's blood bank.

Palo Alto police are presently investigating the incident, but no suspects have been named.

Dr. Kulhanek is a first-year resident in medicine. He is a graduate of the University of Colorado. He came to Stanford in 1968 where he completed his medical internship.

STANFORD -- A public health warning was issued today by Stanford University Medical Center following the illegal removal of an extremely dangerous experimental drug from its premises.

The drug, labeled M99-Etorphine, is contained in five glass vials, each containing 1/2 ounce in a crystaline form. It was locked in a safe along with money and other narcotics, all of which were stolen sometime between last Wednesday and this morning.

Officials stressed that the drug can be absorbed through the skin and the simple act of breaking the vial in which it is contained would be fatal. The drug has a potency of 5,000 to 8,000 times that of morphine and causes immediate cessation of respiration.

Police, who are investigating the theft along with University officials, urged whomever has the M99 to deposit the vial or the unopened safe at a certain location, and then notify police.

The light brown safe measures 14x14x12 inches, and weighs approximately 300 pounds.

statement/ Dr. Bunker

Dr. John Bunker, chairman of the Department of Anesthesia at Stanford University School of Medicine, said the drug was planned to be used as part of a series of studies of drug addiction in animals. The studies were to be done under the auspices of the National Research Council committee on drug dependence.

The drug is manufactured by American Cyanamid Company of Princeton, New Jersey.

Dr. Bunker said there is no published work about the use of the drug in humans and its potency is not known.

M99 is a thebaine derivative chemically related to morphine. By definition, it is considered a narcotic. The synthesis of M99 was the result of a systematic chemical effort to produce a material with analgesic (pain-relieving) propertiesx similar to morphine but without the unwanted side affects.

Among safety procedures recommended by the manufacturer is that no individual work with the drug alone in the laboratory. There should be at least two people ~~xxxxxxx~~ together at all times.

~~Instructions further stipulate that workers should were rubber gloves~~

STANFORD--Dr. William C. Dement, professor of psychiatry and pioneer in sleep and dream research at Stanford University School of Medicine, has been named Thomas William Salmon lecturer by the New York Academy of Medicine.

Dr. Dement was selected for his outstanding contributions to his specialty. In his work with dreaming cats, and psychiatric patients, Dr. Dement has uncovered clues that lend support to a tempting theory that schizophrenia may be the result of a biochemical defect in the patient.

He believes that an abnormality in the function of an essential brain chemical called serotonin gives rise to abnormal behavior by allowing patients to dream while awake.

Dr. Dement presented his findings in a two-part lecture given Wednesday at the New York Academy of Medicine.

The lectureship honoring the late Dr. Thomas William Salmon, a New York physician and leader in the field of psychiatry, was established to recognize each year the specialist in the field of psychiatry, neurology or mental hygiene, in this country and abroad, who has made an outstanding contribution to his specialty.

Dr. Dement who is also a recipient of the Hofheimer Prize of the American Psychiatric Association, is currently working under a grant from the National Institute of Mental Health on the combined physiological-neuropharmacological and biochemical investigation of the basic mechanism of dreams and sleep. He is the co-founder of the Association for the Psychophysiological study of sleep, and he is the author of more than 80 scientific papers on the subject of sleep and dreams.

The Salmon lectures will be published by the New York Academy of Medicine in book form.

STANFORD -- Dr. George E. Burch, one of the nation's leading cardiologists, will deliver the sixth John Kent Lewis Lecture at Stanford University School of Medicine Dec. 8.

He will speak on "Viral Valvulitis" at 4:15 p.m. in Room M106 of the medical school.

Dr. Burch, professor and chairman of the department of medicine at Tulane University School of Medicine in New Orleans, La., has made scientific contributions to the field of cardiology for 30 years. These are covered in over 500 publications and 12 books on cardiology and electrocardiography.

In addition to his research on the effects of viruses on the heart, Dr. Burch is noted for his studies of the effects of climate on the cardiovascular system of man, heat and water loss from the skin and lungs, the aging process and electron microscopic studies of heart muscle and valves.

Dr. Burch is a past president (1968) of the American College of Cardiology. In 1961, he founded the Association of University Cardiologists and at present he is editor of the American Heart Journal. Last year he was named a Master of the American College of Physicians.

A native of Louisiana, Dr. Burch was born in Edgard and received the M.D. degree from Tulane University School of Medicine in 1933. He joined the faculty there after interning at Charity Hospital in New Orleans where he also received his advanced clinical training. He also was a postdoctoral fellow at the Hospital of the Rockefeller Institute for Medical Research from 1939-41. Dr. Burch was appointed to his present position at Tulane in 1947.

Dr. Burch's lecture is dedicated to the memory of Dr. John Kent Lewis, professor of medicine and chief of the Stanford Medical Service in San Francisco who died in 1961. Dr. Lewis, with Stanford professors A. W. Hewlett and George D. Barnett, published some of the early work on vascular sounds, exercise and respiration. The lecture is open to members of the medical community and public.

ADVANCE FOR P.M. RELEASE WEDNESDAY, DECEMBER 3, 1969

Stanford -- A new and highly sensitive test to rule out the possibility of acute rejection in kidney transplants has been developed by Stanford University scientists.

"By using this test, which determines whether the potential kidney transplant recipient has developed antibodies in his blood which will fight a newly transplanted kidney, we are now able to know which patients have the best chance of having a successful transplant," Dr. Zoltan Lucas, assistant professor of surgery at Stanford University School of Medicine said today (DEC. 3). Dr. Lucas spoke at a transplant symposium during the 51st Annual Meeting of the American Society of Oral Surgeons in San Francisco.

"Correlation of data from the new test has shown that the possibility of a patient acquiring these antibodies is directly related to the length of time the patient has been maintained on an artificial kidney machine (hemodialysis)," Dr. Lucas stressed.

A study by Stanford physicians has shown that 7 patients on dialysis less than three months, who received markedly mismatched kidneys from dead donors, did better than 15 patients who received better tissue matched kidneys but had been on the artificial kidney for longer than three months. The latter patients had developed antibodies which killed the kidneys within the first week.

"It is better to transplant a kidney into a recipient as soon as possible, regardless of the tissue match, than it is to search and search for the 'perfect' match, sometimes for years, while keeping the patient on dialysis, building up antibodies that will probably cause rejection of the kidney when it finally is transplanted," Dr. Lucas said.

He explained that the normal kidney performs two bodily functions. One is to remove poisonous wastes from the body in the urine, and the other is to manufacture certain hormones. Patients who have lost the function of their own kidneys are kept alive until a donor kidney is available by removing the poisons by dialysis.

However, the artificial kidney cannot make the necessary hormones, Dr. Lucas pointed out. One such hormone, erythropoietin, simulates the bone marrow to produce red blood cells. Therefore, the patient on dialysis requires frequent blood transfusions to give him the red cells not being produced by his body.

"Through many blood transfusions, the body tends to develop harmful antibodies against foreign organs, including the transplanted kidney and heart," the surgeon said. Therefore, the longer an individual is on the artificial kidney, the more often he needs blood; the more blood he receives, the more his body will tend to reject, through antibodies, any transplanted tissues or organs."

"At present, there is no method of preventing this type of rejection once the antibody level is too high," according to Dr. Lucas. "If a patient has developed these antibodies, it is better that he not have a transplant, but remain on dialysis from then on."

-more-

Dr. Lucas pointed out that the most successful type of kidney transplant is that in which a patient receives a kidney from a parent or brother or sister whose body tissue is similar to his, thus reducing the possibility of rejection.

"Very often, however, it is impossible to obtain a kidney from a relative," he said. "Often members of a family of a kidney transplant patient also have some kind of kidney disease or have other illnesses or family obligations, that rule them out as donors."

In this situation surgeons then must rely on kidneys from cadavers and have traditionally laid major importance on tests to be sure that the tissue of the donor matches closely the tissue of the potential recipient. Some patients may have to wait for years for a well-matched kidney and in the meantime, be kept alive by the artificial kidney.

"While the closeness of the tissue match between donor and recipient is important and preferable when possible, our studies have shown that this importance diminishes after the recipient has been maintained by the artificial kidney for longer than three to six months," Dr. Lucas believes.

Dr. Lucas's work has been supported by a grant to the General Clinical Research Center at Stanford from the National Institutes of Health and by private contributions to Stanford's Renal Transplantation Research Fund.

STANFORD -- A new expansion of facilities to treat cancer patients at Stanford University School of Medicine will be named in honor of the late Paul A. Bissinger, Sr., prominent San Francisco businessman and civic leader.

To be known as the Paul A. Bissinger Center for Radiation Therapy, the expansion, which is under construction, brings to fruition Mr. Bissinger's desire to enable more people to receive radiation therapy for cancer at Stanford.

Mr. Bissinger, who died of a stroke in London in October, had been successfully treated for cancer of the lymph node system at Stanford in 1967. Following his therapy in the crowded, overtaxed facilities, he contacted other former cancer patients and interested associates and organized "The Friends of Radiology" to raise funds needed to expand the therapy program.

At the time the Friends of Radiology was formed, Mr. Bissinger said "If we are able to financially help with the expansion of facilities at Stanford, thus giving more cancer victims the chance we were given, perhaps our debt of gratitude will partially have been paid."

The group raised nearly $500,000 which has been matched by State and Federal funds. The expansion includes a new building which will house administrative offices and personnel and patient support facilities such as examining rooms. The present quarters of the Division of Radiation Therapy are being remodeled to accommodate two new medical linear accelerators which produce high-energy X rays for treatment of cancer. One of the new models will replace an older prototype accelerator which has been in use since 1956, when it was first adapted for medical use by Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology at Stanford.

The new building and equipment will allow for the treatment of 25 to 30 per cent more patients. At present 2,400 treatments for various types of cancer are given monthly at Stanford with existing equipment and personnel operating 10 hours each day. The daily patient load averages 141 persons and over 1,300 new patients are treated each year.

Mr. Bissinger was a member of the San Francisco Police Commission, serving as president in 1960 and 1962. He also was a past president of the San Francisco Chamber of Commerce.

Among his other activities were as vice president of the San Francisco Musical Association and a former president of the Society for Asian Art. He also was a member of the board of trustees of the World Affairs Council of Northern California and a director of the National Conference of Christians and Jews.

A 49-year-old man from Mountain View became the 20th heart transplant patient today at Stanford University Hospital.

He is James A. Marshall, 1438 Phyllis Ave. Marshall, an interior decorator, received his new heart from an anonymous donor in a 4-1/2 hour operation performed by the Stanford heart transplant team. Marshall is reported in satisfactory condition.

The patient had suffered from deterioration of the heart muscle following a massive heart attack in August. He and his wife, Mildred, have four daughters, Mrs. Eleanor Swicegood, 29, Martinez; Mrs. Carrie Hart, 27, Seattle; Mrs. Nancy Young, 23, Sunnyvale; and Mrs. Liz Sooter, 20, Mt. View. Marshall's parents, Mr. and Mrs. F. E. Marshall, live in Sunnyvale.

Before moving to California nine years ago, the Marshalls lived in Salem, Oregon for 15 years.

In addition to Marshall, Stanford has seven other surviving heart transplant patients, six of whom have been discharged from the hospital to resume a normal life.

STANFORD -- A Stanford University anesthesiologist says the United States has too many surgeons.

He poses the question of whether or not an excessive number of surgical operations is performed, implying a variation in the theme of Parkinson's Law: where there are too many surgeons they will fill their time by doing too many operations.

Dr. John P. Bunker says he is concerned about the problem because the United States has an excessive number of physicians in some specialties and not enough in others.

He wonders if the country provides "luxury" surgery for the well-to-do while failing to provide proper care for the poor.

Dr. Bunker is professor and chairman of the department of anesthesia at Stanford University School of Medicine. His views appear in the January 15 issue of the New England Journal of Medicine.

He draws his conclusions from a comparative study of operations and surgeons in the United States and in England and Wales.

"The American surgeon is more aggressive," he writes. "He appears to hold higher expectations of what surgery can offer in the treatment of disease, whereas the British surgeon is more modest in his expectations, possibly more realistic, but also possibly missing opportunities for surgical care."

American surgeons operate nearly twice as often as the English and Welsh, Dr. Bunker reports, and offers statistics to support his thesis.

He finds that the number of elective operations (much higher in the U.S.) reflects in part the philosophical differences of U.S. and British surgeons.

For example the rate for radical mastectomy (operation for cancer of the breast) for the U.S., which is twice that reported in England and Wales, presumably reflects the difference in enthusiasm for this procedure in the respective countries.

"Given the choice of administering or withholding therapy, whether the therapy is prescribing drugs or performing an operation, the American physician appears likely to choose active therapy," Dr. Bunker says. "The British surgeon, faced with the same choice and carrying a heavier work load, is apt to avoid surgery if the indication is in question."

Dr. Bunker shows that socioeconomic considerations, method of payment and organization of medical services also may account for fewer operations in Great Britain.

Under the British National Health Service, "the surgeon is a true consultant," Dr. Bunker explains. "He sees patients only as they are referred to him by the general practitioner or internist, and he is hospital based.

"The American surgeon, by contrast, may function as consultant exactly as his British counterpart, but he may also accept patients without referral, or he may be the primary physician-general practitioner, referring the patient to himself for surgery, and thus creating his own demand."

-more-

Dr. Bunker thinks that the question of referral is important in patient care because surgeons and nonsurgeons are apt to have very different ideas about indications of surgery.

"This is inherent in their specialty training," he comments, "and is reflected at its worst when surgeon and internist isolate themselves from each other. The internist often sees himself as the patient's protector against surgery. But when two different points of view are brought to bear on the problems of a single patient, it is very much to the patient's advantage."

Dr. Bunker offers this example of the effects of consultation in the United States. When a plan for reimbursement of surgical fees was offered to the United Mine Workers some years ago, the number of surgical bills increased . The Mine Workers Fund was concerned with the large amount of what appeared to be unnecessary surgery, namely gynecologic operations and appendectomies.

When a requirement was added that all operations be endorsed by preoperative specialist consultation, the number of operations fell by as much as 75 per cent for hysterectomies, 60 per cent for appendectomies, and 35 per cent for hemorrhoidectomies.

Dr. Bunker is not the only physician to question surgical practices in recent months. Dr. Charles E. Lewis of the Harvard Center for Community Health and Medical Care raised similar questions in an article in the October 16 issue of the New England Journal of Medicine.

Dr. Lewis analyzed records of the Kansas Blue Cross and found three-to four-fold variations in regional rates for the performance of six common surgical procedures. These included tonsillectomies and procedures with more definite indications for surgery such as appendectomies.

"The results," Dr. Lewis concluded, "might be interpreted as supporting a medical variation of Parkinson's Law: patient admissions for surgery expand to fill beds, operating suites, and surgeon's time."

Dr. Bunker believes that group practice (whether privately organized in the United States or as a single large service in Great Britain) is a system that incorporates the wide use of consultation, and encourages a greater emphasis on office care.

"There is evidence," he states, "that these elements lead to improved public health, which in turn leads to a decreased need for hospitalization, including a decreased need for surgery.

"Group practice also provides the opportunity for the more efficient use of medical (and surgical) manpower."

He adds that the method of payment appears to play an important, if unmeasured part. Surgical fees in the United States are much greater than those in other areas of medicine, and the opportunity for large incomes may lure a disproportionate number of physicians into the practice of surgery.

The Stanford anesthesiologist stresses that his findings do not necessarily lead to the conclusion that American surgeons operate more often as the public health might justify. The direct measurement of the quality of medical care is exceedingly difficult, he says.

A more plausible explanation could be that the United States may simply be affording the luxury of surgical procedures that are desirable but not essential.

-more-

Response to Dr. Bunker's study is expected to be wide and varied. An early reaction in the form of an editorial comes from Dr. Francis D. Moore, a prominent Harvard University surgeon.

Writing in the same issue of the Journal, Dr. Moore says that differences in the patterns of surgical practice in the two countries do not indicate a qualitative judgment about which is superior.

"Could there be similar excess of operative dentistry in the United States as compared with England--more fillings, extractions or crowns?" Dr. Moore asks. "What about American pediatrics? The British pediatrician is a relative rarity and acts largely as a consultant to the physician for unusual illness. One might conclude that American pediatrics was grossly overexpanded.

"We need more information on the extent to which surgical perfection is achieved in either, neither or both systems."

Dr. Bunker also emphasizes the need for additional data. But this does not alter his conclusion that while U.S. physicians provide the last word in medical care to the wealthy, they have failed to provide basic medical care to the poor.

Decisions on how many surgeons are needed in the United States must be based on a judgment of how much operative treatment the public requires, he asserts.

These decisions must also take into account the limited manpower pool. "More surgeons may mean fewer doctors for other needier medical specialties."

Such evaluation and planning are needed, Dr. Bunker concludes, "to reverse the paradox of a country that provides 'luxury' care for the well-to-do but cannot provide basic medical care for the indigent."

STANFORD -- Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery at Stanford University School of Medicine, has received a 1970 Award for Distinguished Achievement from Modern Medicine Magazine, a national professional journal.

The magazine honored Dr. Shumway for his "painstaking development of cardiac surgery techniques influencing the advent of heart transplantation." He is among 10 men nominated by the medical profession to receive the awards this year.

In December, 1959, Dr. Shumway reported to the medical profession that he and a colleague, Dr. Richard Lower, now on the faculty of the Medical College of Virginia, had performed a heart transplant on a dog, using a new surgical technique. The technique differed from other previously reported methods in that a portion of the recipient heart, containing all the veins leading to that organ, was left in place. The technique, which now is being used in human heart transplantation, was easier technically and shortened the operating time because surgeons only have to suture the heart tissue and arteries.

Dr. Shumway performed the first adult human heart transplant in the United States in January, 1968. Since that time 18 other patients have received new hearts at Stanford. Seven patients survive, six of whom have been discharged from the hospital to resume a normal life.

Dr. Shumway, 46, is a native of Kalamazoo, Mich. He received his medical degree from Vanderbilt University in 1949, and his Ph.D. in surgery from the University of Minnesota. He joined the Stanford faculty in 1958.

Another recipient of the 1970 Award for Distinguished Achievement was a Stanford alumnus, Dr. Jean Oliver. Dr. Oliver, an emeritus professor of pathology at the State University of New York Downstate Medical Center, was cited for his landmark research leading to greater understanding of kidney structure and function. He received the A.B. (1911) and the M.D. (1914) degrees from Stanford.

The Modern Medicine awards are presented annually to men and women selected for their significant contributions to the medical profession. Nominations are made by doctors, deans of medical schools, leaders in medical organizations, and physician members of the magazine's editorial board.

STANFORD--A new program to provide training and job opportunity for disadvantaged groups and to increase the supply of paramedical personnel will be initiated at Stanford University Medical Center.

Implementation of the first phase of the three-fold Intergraded Assistant Program and planning of the second phase will be funded by a $65,000 grant to the Medical Center from the Carnegie Corporation of New York. Awarding of the grant was announced today by the Carnegie Corporation. Long range funding for Phases II and III is still being sought from federal and private sources.

Dr. Thomas A. Gonda, director of Stanford University Hospital, who will administer the new program, said that it is "very imaginative and may well become the prototype for a nationwide effort to train personnel in the paraprofessional areas of medicine." The program was proposed by William R. Stone and Moses Thomas of East Palo Alto, director and assistant director, respectively, of the department of minority relations at the Medical Center.

Using the latest innovative techniques in teaching by computer, the new program is designed to remove one of the major obstacles responsible for exclusion of some individuals from the paramedical fields--the lack of basic education.

Initially participants will be instructed in the basic areas of language, writing, reading and mathematics. They will be granted time off to work at one of four proposed instructional terminals located in the Medical Center. These terminals will handle 240 lessons a day.

Each student will drill by means of the standard teletype keyboard. He will type his name which the computer will acknowledge and then send him the lesson tailored to his ability, which it has previously recorded in its "memory." The computer also on command will provide information on all students' class standing, ability and progress.

Utilization of the computer will be under the direction of Max German, a member of the staff of Dr. Patrick Suppes, professor of statistics at Stanford and a pioneer in the field of computer-assisted instruction. Dr. Suppes and his staff have successfully operated the same type of programs over the past few years in schools of East Palo Alto, Cupertino, San Diego, and Kentucky.

The educational courses provided by the computer will be sufficient to allow students, after completion to be tested through a local district and receive their high school diplomas.

With their basic education requirements completed, interested participants will be able to enter Phases II and III of the Intergraded Assistant Program which will provide training in a variety of paramedical fields. These fields range from laboratory assistant and technician programs, requiring eight weeks of instruction and on-the-job training, to physician assistant programs which have more extensive training requirements.

STANFORD--A search committee to seek a successor for Dr. Robert J. Glaser has been appointed by Stanford University President Kenneth Pitzer.

Dr. Glaser, vice-president for medical affairs and dean of the School of Medicine, announced last fall that he would leave Stanford August 31, 1970 to accept the post of vice-president of the Commonwealth Fund, a philanthropic foundation based in New York.

The search committee will be chaired by Dr. Pitzer. Dr. Eric M. Shooter, professor of genetics will be its vice-chairman.

Members include Drs. Paul Berg, biochemistry; Carl Djerassi, chemistry; Count Gibson, community health and preventive medicine; David Korn, pathology; G. Robert Mason, surgery; Keith B. Taylor, medicine; and two medical students and one member of the house staff yet to be named.

"The search committee will meet very shortly to begin its task and would welcome any suggestions about possible candidates for this important and crucial position in the Medical School," Dr. Pitzer wrote in a letter distributed today to medical school faculty, and members of the medical community associated with Stanford University Medical Center.

These include Stanford medical alumni officers, the Stanford University Hospital board of directors, the Palo Alto Medical Clinic and Palo Alto Medical Research Foundation, the three Neighborhood Health Centers in East Palo Alto, Alviso, and King City, the Menlo Medical Clinic, Santa Clara Valley Medical Center, and Palo Alto Veterans Administration Hospital.

Transplant #19 January 3, 1970

A 40-year-old man from Mill Valley is in satisfactory condition today after receiving a transplanted heart last night (January 3) at Stanford University Hospital.

He is William Van Buuren of 112 E. Strawberry. Van Buuren received his new heart from an anonymous donor in a 4-1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

Van Buuren, a builder's hardware estimator, has suffered heart disease for the past 16 months. He and his wife, Corry, have three children, Caroline 8, Martina, 10, and Robert, 13.

Van Buuren is the 19th heart transplant patient at Stanford. Six other patients survive, all of whom have been discharged from the hospital to resume normal lives.

STANFORD -- Stanford University Medical Center and the Epilepsy Foundation of America will co-sponsor a two-day conference on epilepsy Friday and Saturday, February 27 and 28 at Rickeys Hyatt House in Palo Alto.

The Saturday sessions will be open to the public. Parents of epileptic children, psychologists, social workers, physicians, speech and physical therapists, and others with a special interest in epilepsy will be welcome to attend, according to conference chairman Dr. Barry R. Tharp, assistant professor of neurology at Stanford.

Saturday morning's program, beginning at 9 a.m., will include behavioral and personality aspects of epilepsy, and recent developments in the care of the epileptic.

At one of the Friday afternoon sessions, L.S. Sampson, Executive Director of the Vancouver Neurological Center, Vancouver, British Columbia, will describe the educational program that the Center offers parents. The program's objective is to weld parents and physicians into a team which can achieve a wholesome environment for the child, enabling him to be accepted for himself, not as a medical oddity.

Saturday morning's speakers will be Dr. Douglas Crowther of the University of California School of Medicine at San Francisco, who will talk about the Northern California Epilepsy Program; Dr. J. William Knox, also of UCSF, whose topic is "The Borderlands of Epilepsy;" Dr. Mardi Horowitz of San Francisco's Mt. Zion Hospital and Medical Center, who will talk on "Epilepsy and Personality;" and Dr. Leon Oettinger, Jr. of San Marino, California, speaking on "Behavioral Problems in Epilepsy."

The conference's purpose is to disseminate information on experimental, social, and rehabilitative advances in the care of epileptics, and to open channels of communication between lay and professional groups working toward the same goals, Dr. Tharp said.

Editors: The following story is released jointly by Stanford University School of Medicine and NASA-Ames Research Center. Photographs available on request.

ADVANCE FOR P.M. RELEASE FRIDAY, FEBRUARY 27, 1970.

STANFORD -- Scientists from the Stanford University School of Medicine and NASA's Ames Research Center have teamed up and successfully tested a new application of sonar (often called ultrasound) that can pry out secrets about the functioning of the human heart.

The new use of sonar, reported today at the meeting of the American College of Cardiology in New Orleans, can provide fundamentals of the heart beat and blood circulation heretofore unobtainable without passing a catheter (a long thin tube) into one of the heart chambers.

That procedure, known as cardiac catheterization, requires many hours and the patient is usually hospitalized. Additional laborious procedures involve the taking of X rays, and blood samplings.

By contrast, ultrasound studies of the heart can be done by a well-trained person in the physician's office or at the patient's bedside in a matter of minutes. The technique can be applied as a screening procedure for patients with known or suspected heart disease. And it can be used to monitor precisely the heart's healing process in patients recovering from open heart surgery or from a heart attack.

Unlike standard monitoring devices, sonar measures precisely the amount of blood which is pumped out of the heart at each contraction of the heart muscle. It also measures heart size and the backward flow of blood which indicates that the patient has a defective heart valve.

The Stanford-NASA researchers conducted sonar studies in 51 patients undergoing standard catheterization. Their finding, obtained by ultrasound, correlated "reasonably well" with the degree of heart disease detected by the standard method, they reported.

The work began as a result of interest by NASA in ultrasonics as one of several techniques for using external instrumentation for medical research during manned space flights, and coincided with interest in ultrasonics at Stanford.

-more-

The new use of sonar was described by Dr. Richard L. Popp, a postdoctoral fellow in cardiology at the Stanford University School of Medicine, and Dr. Donald C. Harrison, associate professor and chief of cardiology at Stanford. Working with them on the project is Dr. Harold Sandler, chief of the biomedical research branch at the Ames Center, Mountain View, California.

The Stanford work is supported by grants from NASA-Ames, the National Institutes of Health, and the American Heart Association.

NASA is seeking devices to collect and record information on human heart action during space flights, according to Dr. Harrison, the principal investigator.

Now that the use of sonar in heart monitoring has proved its value, work will begin to build ultrasound devices that are small enough to be carried in orbiting space laboratories.

In addition, scientists will study the use of computers for storage, retrieval, and instant interpretation of ultrasound recordings received on earth.

The instrumentation work will be done by researchers at Ames. Testing of the new devices in human patients will be conducted by Dr. Harrison and his associates at Stanford.

The sonar recordings on heart patients in the recent Stanford study were made by using a commercially available machine which emits and receives high-frequency sound waves.

As sonic impulses were bounced against front and rear walls of the heart, they were recorded and converted into electrical signals which were displayed on a television screen.

From the patterns of ultrasonic echoes, taken when the heart is relaxed and when it contracts, the researchers developed a formula enabling them to calculate precisely the volume of blood ejected by the heart, and also determine the presence of abnormalities.

Dr. Harrison said that from a medical standpoint the technique is promising and warrants further investigation to refine it "because it is painless, simpler, and safer, and less costly to the patient than present methods."

Ultrasound is also being used at Stanford to detect heart changes that lead to early rejection in heart transplant patients.

ADVANCE FOR P.M. RELEASE SATURDAY, FEB. 28, 1970.

STANFORD -- Long-term evaluation has shown that the transplanted human heart functions well and that rejection of the graft can be detected and controlled in most cases, a Stanford University cardiologist said today.

Dr. David Clark, a member of the heart transplant team at Stanford University Medical Center, explained the thorough follow-up of patients after discharge from the hospital. He spoke today, (SATURDAY, FEB. 28) at the American College of Cardiology meeting in New Orleans.

"Twenty patients have received transplanted hearts at Stanford with eight presently surviving," according to Dr. Clark. "Of the eight surviving patients, seven have been discharged from the hospital and lead near-normal lives."

"Three of the survivors were transplanted over a year ago and our longest survivor is now a year and a half post-transplant," he said. "In addition, seven have survived six months and 11 patients lived at least three months with their new hearts."

"Our experience has shown that chronic rejection is the important factor in late postoperative survival and in determining the functional capacity of the heart," Dr. Clark said. Chronic rejection, he explained, appears to take place slowly over a long period of time. It results in an accumulation of tissue deposits on the walls of arteries in the heart. If severe, this accumulation can eventually cut off the blood supply to areas of the heart including the conduction system and natural pacemaker of the heart.

"Our follow-up of these patients has been directed toward detection of signs of chronic rejection and toward the diagnosis and treatment of late acute rejection which directly damages the heart muscle," he said.

"After discharge from the hospital, we examine the patients twice weekly for at least six months and at weekly intervals thereafter," Dr. Clark explained. "Clinical examinations consist of appropriate history and physical examinations. Electrocardiograms (EKG) are taken also during periods of both rest and exercise on a stationary bicycle."

-more-

Dr. David Clark/control of rejection

"Using this close and continuous monitoring, we have been able to diagnose and treat seven episodes of acute rejection in the late postoperative period," the cardiologist said. "The treatment proved successful in six of the episodes although one was unresponsive to therapy and was responsible for the death of the patient."

To aid in the detection of chronic rejection, the Stanford physicians are using a small portable tape recorder which supplies them with a continuous, 10-hour electrocardiogram recorded during periods of rest and activity. Each patient wears the recorder two days a month.

"With the data provided by the EKG recording over a substantial period of time, our ability to study the overall function of the transplanted heart and to detect heart arrhythmia, or an irregular heart beat, is greatly increased," Dr. Clark said. "The presence of arrhythmias may be an indicator of chronic rejection."

One patient whose EKG did indicate an irregular beat had a battery-operated pacemaker implanted to stabilize his heart rate and has continued to lead a normal, vigorous life.

"A regular schedule of physical exercise may play an important role in determining the functional response of the transplanted heart to stress," Dr. Clark said.

He cited the case of one patient who regularly exercised for 10 months after his heart transplant. Then a job change caused him to lead a more sedentary life and to neglect his exercise program.

"Our testing of the physical stamina of this patient during the time when he was not exercising regularly found him to have difficulty breathing and excessive perspiration. The same test, given when the patient was exercising regularly, found that the physical exertion was easily tolerated," Dr. Clark pointed out.

Three of the Stanford patients have undergone cardiac catheterization one year after their operation. In this procedure, a long thin tube is passed through an arm vein to the chambers of the heart. The patients participate in exercise which gives precise information on the heart function during periods of both rest and activity.

"Catheterization has shown that all three patients have normal blood flow and pressures in the various chambers of the heart and that the heart size is within normal range," Dr. Clark said.

"Another purpose of this procedure has been to check for reinervation between the transplanted heart and the central nervous system of the patients," Dr. Clark said. "Our data indicate that this has not taken place."

"The transplanted heart is able to respond to increased demands for cardiac output during exercise through substances circulating in the blood, but the maximum rate is attained more slowly and the return to resting heart rate is likewise more gradual than in the normal individual," Dr. Clark concluded.

STANFORD -- Stanford University School of Medicine will offer tutoring help to foreign medical graduates who wish to apply for a California state license.

The tutorial program will get underway at Stanford the first week of March, according to Dr. Barbara Arons, coordinator of the Study of Women in Medicine at Stanford.

The first group to enroll will be 12 women doctors who were recently located through a Stanford survey. Purpose of the survey, supported by a Macy Foundation grant, was to study the lives and professional activities of women M.D.'s.

Tutorial help will not be limited to women, Dr. Arons said. She will welcome inquiries from men physicians as well.

As a first step toward licensure, physicians must take the Federal Licensing Examination, or FLEX, adopted in California last year, which is an objective type test rather than the essay type most foreign graduates are used to taking. The tutoring program is designed to familiarize the foreign graduates with the professional standards required by the State, and update their clinical skills and knowledge of basic science.

One or two years of internship, plus an oral examination, complete the requirements for full licensure in California.

The tutorials will be individual, one-to-one hourly sessions once a week with teachers who will direct the medical graduates' reading and test them on their progress.

The first group will aim toward a FLEX testing date of next December, Dr. Arons said.

Nationalities represented in the group are: Mexican, British, Indian, Czechoslovakian, Venezuelan, German, Phillippine, Korean and Swiss. The women have specialties in gynecology and obstetrics, pediatrics, anesthesiology, internal medicine and psychiatry. Most of them immigrated to the U.S. because their husbands were attracted by career opportunities here.

Foreign medical school graduates constitute about 18% of the annual addition of physicians to the medical profession in this country.

"At a time when there is a critical shortage of physicians, we view this tutorial program as a major contribution to meeting the nation's medical manpower needs as well as an educational opportunity for the individual physicians involved," says Dr. Arons.

STANFORD -- Dr. Herbert C. Schwartz, 44, has been named chairman of the department of pediatrics at the Stanford University School of Medicine.

His appointment, effective immediately, was announced today by Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine.

Dr. Schwartz succeeds Dr. Norman Kretchmer, who resigned a year ago as department chairman to return to full-time teaching and research in human biology.

Dr. Schwartz is professor of pediatrics and has been a member of the Stanford medical school faculty since 1960.

A native of Hamden, Conn., he received his A.B. degree from Yale University in 1948 and his M.D. degree from the State University of New York College of Medicine in 1952. He served part of his residency at Stanford in 1954-55.

His special field is pediatric hematology, with emphasis on the care of children with leukemia. His major area of research is the synthesis of hemoglobin during human development, particularly as it relates to causes of anemia.

His is also a Markle Scholar in Academic Medicine.

Dr. and Mrs. Schwartz live in Palo Alto. They have a son and two daughters.

STANFORD -- A Stanford University surgeon says that 90 per cent of deadly hepatitis from blood transfusions can be traced to the use of commercial blood, and urges federal action to stop its use.

Dr. J. Garrott Allen, professor of surgery at the Stanford University School of Medicine, wants the Division of Biologics Standards of the U.S. Public Health Service to take steps to remove commercial blood from the market or to label it as a "high-risk product" if its use must continue.

"This action is essential to protect the consumer," Dr. Allen said. "If the blood carries a warning, the patient's doctor can make a reasonable choice."

At present there is no federal requirement to distinguish commercial from volunteer blood. (Donors of commercial blood receive a payment from a commercial blood establishment. Volunteer blood is given without payment to community blood banks.)

And there is no reliable test which can detect those capable of transmitting the hepatitis virus from donors who cannot, he said. Dr. Allen is internationally known for his research in blood and hepatitis.

He said in the past 10 years, his laboratory has published overwhelming evidence pointing the enormous differences in the safety of volunteer and commercial bloods.

Two recent reports by researchers at the University of Washington School of Medicine in Seattle, and the National Institutes of Health* have indicated that hepatitis is more prevalent when sources of blood used in open heart surgery include a substantial number of "skid row" donors.

"These data strikingly illustrate my previous observations in which the risk of hepatitis was 10 to 25 times greater for commercial blood than for voluntary blood," Dr. Allen said. "Yet there has been little action--official or unofficial--to protect the public."

Dr. Allen estimates that more than 5,000 cases of infectious hepatitis are being caused in California alone each year by transfusions of blood from paid donors.

He believes that use of volunteer blood exclusively could eliminate 90 per cent of the cases of hepatitis in patients who receive transfusions, and he is conducting a one-man campaign to bring the problem to public attention.

---

* One study, published in the Annals of Surgery in 1969 by the Seattle group, found no cases of hepatitis after open heart surgery when blood transfusions were from volunteers. In cases in which commercial blood was used, the attack rate of hepatitis was 31 per cent.

The NIH study, published in the Journal of the American Medical Association last month, found 51 per cent of hepatitis in recipients of commercial blood, and none among a group receiving blood from volunteers.

-more-

" If the public were aware of these differences in risk, they would be more willing to participate in a volunteer program than they have in the past," he said.

"It is shocking," he added, "that in the United States only three per cent of our population provides the estimated 7 million units of blood that are given annually."

Deficits of blood are presently made up by purchase of blood from high-risk population--prison donors, skid-row volunteers, and hippie addicts, Dr. Allen explained.

He said a physician working with the Haight-Ashbury Free Medical Clinic told him recently that "the sale of blood is a well known and not infrequently used means of obtaining income by these young people who are often in difficult economic circumstances."

Their economic needs, according to Dr. Allen, are such that they are willing to give blood for a little as $4 to $6 a unit compared to donors who receive as much as $25 a unit in some establishments.

"It is evident," he said, "that the usual questions asked of donors and the physical examination required by commercial blood banks, do not exclude enough of this high-risk population to reduce the rate of hepatitis among patients who receive the blood."

The practice of making up blood deficits from high-risk donors poses a serious ethical question, if not a legal one, Dr. Allen said. This is the assurance that a volunteer blood donor, contributing to his blood club or to his community blood bank, will in turn receive blood from a similarly low-risk carrier population, if he needs blood later.

"Volunteer donors who do not receive such a guarantee should refuse to give blood," he said.

"Under most circumstances today, blood replacement by relatives and friends of patients is not required," Dr. Allen explained. "To provide enough volunteer blood for everyone, such a requirement would be a first step."

He believes that change must come through "a conscious, sustained public effort to promote volunteer blood giving at the community level."

STANFORD -- The John A. Hartford Foundation, Inc. of New York has made a three-year grant of $140,544 to the Stanford University School of Medicine to improve methods for the diagnosis and study of Hodgkin's disease.

The award was announced jointly today by the Foundation's president, Harry B. George, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine.

Purpose of the project is to utilize electron microscopy and other sophisticated basic science techniques to study the natural history of the disease, and to use these methods to increase the accuracy of diagnosis. The project is under the direction of the Department of Pathology.

Dr. Ronald F. Dorfman, associate professor of pathology, is the principal investigator. He will be assisted by Dr. Richard L. Kempson, associate professor of pathology, and Dr. Charles P. Bieber, a postdoctoral fellow in pathology. Mrs. Dede Rice and Mrs. Ann Mitchell, senior research assistants, will also be associated with the project.

Hodgkin's disease is a form of cancer affecting the lymph glands and tissues which play a part in the body's ability to fight infection.

Treatment of the disease with radiotherapy and drugs has become increasingly successful in recent years, but evaluation of the response to therapy depends a great deal on diagnostic precision.

"Presently, the accurate diagnosis of Hodgkin's disease depends more on the pathologist's experience than on scientific method," Dr. Dorfman said.

He cited a British study in which a significantly high number of diagnostic errors were disclosed on reviewing cases diagnosed as Hodgkin's disease.

To make a diagnosis, the pathologist examines a piece of the suspected tissue in the light microscope. He must look for the presence of Reed-Sternberg cells, an aberrant cell without which the diagnosis of Hodgkin's disease cannot be made.

The pathologist must base his opinion not only on the presence of these cells, but also on observations of the environment in which they are found, and on certain cellular patterns.

-more-

Using these criteria, he makes a diagnosis of Hodgkin's disease as distinct from other forms of lymphoid cancer. The procedure often involves two or three pathologists for considerable periods of time, searching microscopic slides for Reed-Sternberg cells.

"This is a very difficult problem for pathologists who do not see a large number of bippsies from patients with Hodgkin's disease," Dr. Dorfman explained. "At Stanford and other medical centers which treat large numbers of patients with this disease, pathologists are developing greater expertise. Still this does not eliminate the problem of subjectivity in diagnosis."

Making a precise diagnosis is further complicated by other diseases which simulate Hodgkin's disease, Dr. Dorfman continued.

In patients with infectious mononucleosis, for example, cells have been found which resemble Reed-Sternberg cells. Anticonvulsive drugs and the smallpox vaccine may also produce pathologic changes resembling Hodgkin's disease in lymph glands.

Dr. Dorfman said that Stanford University Medical Center possesses well-established and renowned radiotherapy and oncology services which treat large numbers of patients with Hodgkin's disease and other malignant tumors. These services provide an abundant source of pathologic material for both diagnostic and investigative studies.

Stanford's area of investigation will include:

. Application of electron microscopy to better define the structure of aberrant cells found in Hodgkin's disease, and their response to various forms of therapy.

. Development of effective labeling methods using new cell-staining techniques.

. Tissue culture studies, including use of radioactive tracers, to observe growth patterns of abnormal lymphoid cells.

. Chromosome studies to define the genetic makeup of malignant cells.

. Immunologic studies to determine if serum from patients with Hodgkin's disease contains tumor-specific antibodies. The presence of a specific antibody might provide a new method for making an accurate diagnosis and provide further clues as to the nature of the disease.

"Development of a truly scientific approach for accurate diagnosis will mean a great deal to the patient," Dr. Dorfman said. "Incorrect diagnosis prejudices the patient's chances of receiving treatment for cure."

STANFORD -- "Struggling beginning skiers are the most prone to injury and the greatest risk period for them is the first day of skiing," says a Stanford University orthopedic surgeon.

"Poor judgment is an evident correlation of most accidents," according to Dr. Richard Spademan. "If one considers that less than five per cent of reported injuries involve faulty equipment, unexpected release of bindings, obstacles or collisions, responsibility for injury must be placed with the skier whose judgment of conditions is impaired or ignored."

Dr. Spademan has spent the past four winters photographing falls and interviewing injured skiers at Squaw Valley, Calif.

"Perhaps the greatest problem relative to these accidents is the skier's opinion about his own competence and the necessary preparations for safe skiing," the physician said. "Many skiers also suffer from a 'sense of indestructability' so prevalent in the late teenage years."

He found a greater incidence of injury was evident in the younger age group. "While 23 was the mean age of all skiers interviewed, over 50 per cent of the injuries were sustained by those less than 21 years of age," Dr. Spademan reported.

While there is a substantial reduction of injuries after one year of experience, Dr. Spademan pointed out that there are also problems which impair the judgment of the more advanced skiers.

"The past 10 years have brought an escalation of medical problems for this group because advances in equipment and technique have been oriented toward racing with a disregard for the factors that limit the recreational skier's efficiency. The stability and durability of skis, bindings and boots allow the development of speeds and perilous situations that cannot be sufficiently controlled by human reactions," he said.

An ardent skier himself, Dr. Spademan said that in comparing the relationship of ski binding release to injury, 55 per cent of the injured group said that their bindings had failed to release. Another 35 per cent reported that their bindings had released, with three per cent noting accidental release. (No information was available in six per cent of the cases.)

"It is evident that in most instances the injury was sustained before the ski boot and ski assumed a position that would allow release of the boot from the ski," Dr. Spademan said. "We also found that release of the boot from the ski is dependent upon the sex and competence of the skier."

"Binding release occurred more frequently among males and as the level of competence increased," he said. "Women may sustain injury more readily because the force required to disengage the ski boot from the binding tends to overcome their injury threshold."

In the Squaw Valley surveys, 46 per cent of the injured skiers were female although they constituted only 42 per cent of the skiing population.

Dr. Spademan has developed a revolutionary new binding that does away with the conventional toe piece except for a small pad that levels the boot. This enables the boot to slide off in almost any direction, especially forward, without becoming tangled.

"With a 20 per cent growth rate in the number of beginning skiers each year, education, including a greater effort toward organized ski instruction is needed to reverse the injury trend," Dr. Spademan concluded.

STANFORD -- Nobel Laureate Joshua Lederberg, professor of genetics at the Stanford University School of Medicine, will join three other prominent scientists in a panel discussion on radioactive pollution Friday (February 13).

The panel discussion, entitled "Environmental Radiation Hazards and Nuclear Energy," will be at 8 p.m. in Bishop Auditorium of the Graduate School of Business. The meeting is open to the public.

Sponsor of the event is the newly formed Stanford Committee for Environmental Information, chaired by Dr. John W. Farquhar, associate professor of medicine.

Appearing with Dr. Lederberg on the panel will be Dr. Daniel B. Luten who will discuss "Energy in the Future;" Dr. John W. Gofman who will talk about "Health Hazards;" and Dr. Dean E. Abrahamson who will speak on "Waste Releases--Economics and Politics."

Dr. Luten is a lecturer in geography at the University of California at Berkeley.

Dr. Gofman, who recently created a controversy by suggesting a 10-fold reduction in present radiation exposure guidelines for the population at large, is professor of medical physics at the University of California.

Dr. Abrahamson, assistant professor of anatomy at the University of Minnesota, is one of the concerned scientists who recently laid down a barrage of criticisms in the press, in public meetings and in Congress, against Atomic Energy Commission regulations to cope with radioactive wastes from nuclear power reactors.

Specifically, Dr. Abrahamson, who is also president of the Minnesota Committee for Environmental Information, charged that a nuclear generating plant now under construction near Monticello (Minn.), some 33 miles upstream on the Mississippi River from St. Paul and Minneapolis, might exceed the AEC's effluent standards; that AEC standards are too lax anyway; and that plans for monitoring the plant's contribution to environmental radioactivity are inadequate.

As a result of this effort by Dr. Abrahamson and his group, the Minnesota Pollution Control Agency has limited radioactive discharges from nuclear reactors to levels considerably below those currently allowed by the AEC. If the proposed state restrictions survive a pending court test, the action taken by Minnesota could serve as a precedent for further efforts to crack down on radioactive contamination at the state level.

Dr. Farquhar said the Stanford Committee has chosen the topic of radiation standards because it should concern every citizen interested in the preservation of a healthy environment. By 1990, more than 100 nuclear plants are scheduled to be built in the United States to meet increasing demand for generating capacity.

STANFORD - Concerned about a "lack of direct communication with medical students," the Council (governing board) of the Santa Clara County Medical Society has begun proceedings to open membership in the Society to students at Stanford University School of Medicine.

Disclosure of the proposals to involve students in Medical Society affairs was made today by Dr. R.Hewlett Lee of Palo Alto, president of the Society and a Stanford medical alumnus.

Approval will hinge on ratification of a change in the organization's by-laws by a majority of the Society's members.

The Council also submitted proposals that would allow students to be appointed to Society committees, to have a student-elected representative as a voting member of the Council, and to publish their opinions in the Society's newsletter.

So that better communications can flow both ways, the physicians, in turn, would increase their teaching activities, hold noon seminars, and include the students on the newsletter mailing list.

The proposals are the outgrowth of dialogue which began a year ago, Dr. Lee said. A liaison committee composed of members of both groups worked out the details.

The liaison committee chairman, Dr. Joseph Ignatius of Los Altos, commented that the relationship had been entered into "seriously." He said an active role on the Society's committees "will allow students to participate in a meaningful way, not in a token way, because it is the committees that formulate and carry out policy."

Dr. Lee said the students can offer new ideas and talent in the areas "where the action is." He noted that the scope of committee activities includes representing the local group at state and national meetings, studying health care for the poor, recommending changes in the law, enforcing professional medical standards among the members, planning a weekly educational TV show for doctors in the county, and conducting public health studies such as a current one on environmental planning.

Aware that the chance to inject youthful voices could lead to substantive changes in organized medicine's viewpoint, Dave Sachs, third-year medical student at Stanford and president of the local chapter of SAMA (Student American Medical Association) said: "Our very presence changes the (AMA's) tenor."

He added the County Society has been generous in supporting SAMA activities "chipping in to send delegates to regional meetings, and so forth" but predicted that student participation in the AMA at the local level "and on up" would have "an even greater impact than feedback from SAMA conferences."

The Stanford chapter of SAMA withdrew from national SAMA four years ago "reflecting student disenchantment at being a baby AMA," Sachs said. "But we re-affiliated this year after SAMA's interests changed drastically and it became independent from AMA control."

Jeff Brown, also a third-year student, is president of the Stanford medical student government organization. He sees the new involvement with the County Medical Society as "our chance to do something constructive."

"The ultimate issue," he said, "is what the students of today are going to do with, about or without organized medicine." 2/5/70 ### 2/5/70

STANFORD -- Parents of Children with Neurological Defects will meet at 7:30 p.m., Tuesday, February 10 in Room A335 of Stanford University Medical Center. The speaker will be Rose Grobstein, acting chief pediatrics social worker at Stanford University Hospital.

Children of parents in this group were born with myelomeningocele and in some cases hydrocephalus. The group welcomes new members and is eager to make itself available to other Bay Area parents in the same situation.

Parents who cannot attend the meeting, but would like information about the group may call Mrs. Roger Cummings at 258-6788 in San Jose.

STANFORD -- The Children's Health Council of the Midpeninsula and the Stanford University School of Medicine today announced they have established an affiliation to further common objectives in diagnosis and treatment of handicapped children.

Announcement of the agreement was made by William J. Swanson, board president of the Children's Health Council, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school.

A joint statement by the two institutions said that they are developing a closer relationship:

. to take advantage of an increased information exchange regarding diagnostic techniques in the treatment of children with mental, emotional, and neurological problems.

. to enable staff members and trainees to participate in educational opportunities offered by the two institutions.

. to explore more fully research opportunities into a better understanding of handicapped children and their treatment.

Under the agreement, the Children's Health Council board of directors will continue to set policy governing programs and be responsible for the Council's operations. Staff appointments at the M.D. and Ph.D. levels will be made by the Council from candidates acceptable to the Medical School for either voluntary or full-time faculty appointment.

Some of the future training and research projects will be developed jointly by the two institutions.

Dr. Albert C. Fremont, director of Children's Health Council, termed the agreement "an important step" in establishing an increasing collaboration between the two institutions.

"We are confident that it will help foster new and better training and research programs and will result in the provision of improved services to handicapped children in the community," he commented.

The Children's Health Council of the Midpeninsula is a private, nonprofit organization of professional and volunteer workers who help children with mental, physical, and behavioral problems. It was founded in 1953 by Dr. Esther B. Clark, a prominent Palo Alto pediatrician and Stanford Medical School alumna.

The Council has a clinical and administrative staff of about 30 persons, including pediatricians, neurologists, psychiatrists, psychologists, speech and hearing specialists, physical therapists, occupational therapists, pre-school teachers and social workers. The Council's facilities are located near the Stanford University Medical Center on land leased from Stanford University.

The new agreement brings to five the number of institutions presently associated with the Stanford University School of Medicine. The others include the Palo Alto Veterans Administration Hospital, the Santa Clara Valley Medical Center, the San Mateo County General Hospital and the Stanford Children's Convalescent Hospital.

"Can smog be eliminated?"

This and related questions will be discussed by Dr. Arie J. Haagen-Smit in his talk, "The Battle for Clean Air," Monday (April 6) at Stanford University .

The talk, sponsored by the Stanford Committee for Environmental Information, will be at 8 p.m. in the Physics Tank. The public is invited free of charge.

The Stanford Committee for Environmental Information, chaired by Dr. John W. Farquhar, is a newly formed group of scientists providing analytical reviews of public issues concerning the impact of technology on our environment.

Dr. Haagen-Smit is chairman of the California Air Resources Control Board and chairman of President Nixon's task force on air pollution. He is also professor of bio-organic chemistry at the California Institute of Technology, and has made scientific contributions to the studies of plant growth through the isolation of various plant hormones, and other biologically important substances.

In 1948, Dr. Haagen-Smit studied the irritating air of Los Angeles and found that it contained organic material--mostly hydrocarbons--that were released into the air by automobiles and oil refineries. Although these substances were known to be products of incomplete combusion, they had never before been reported as significant air pollutants.

As a result of further work, Dr. Haagen-Smit concluded that organic material was oxidized through the combined action of oxides of nitrogen and sunlight. In these reactions plant-damaging, eye-irritating, and rubber-cracking materials are formed.

His discovery opened up a whole new field of research into the problem of smog and programs for control of the auto exhaust.

Dr. Haagen-Smit participates as a consultant to many civic and government organizations such as federal, state and county health services, and the Atomic Energy Commission.

STANFORD -- A light-weight bed with a space-age name is providing Stanford University scientists with new information on drugs that affect the heart and heart transplant rejection.

Called a ballistocardiogram (BCG), the apparatus enables the measurement, literally, of the hurling or ejection of blood from the heart, according to Dr. N. Ty Smith, assistant professor of anesthesia at Stanford University School of Medicine and director of the BCG research project. Dr. Smith's work is supported by the National Institutes of Health.

"The first thing that goes wrong with the heart is not its ability to put out a certain amount of blood, but its ability to accelerate the blood into the aorta," Dr. Smith says. "Therefore, the measurement of this ability is a good indicator of the heart's overall function."

He compares good or bad heart function with two cars. While both may be able to eventually travel between two points or at a certain speed, it is the car with "get-up-and-go" from the stop light that performs better.

To record the BCG, a patient simply lies on a cot-like bed weighing four pounds that is delicately suspended from eight 9-1/2 foot wires that extend through the ceiling of the BCG laboratory. The apparatus works on the principle of a pendulum, with the long suspension wires giving the BCG bed a natural swinging frequency that is lower than the natural heart beat of the subjects to be studied.

"This design, with the bed so lightly coupled to earth, enables us to measure the movements of the body caused by acceleration of blood in the body," Dr. Smith points out. The movement is measured by a highly sensitive accelerometer, a direct spin-off of the space program, which is attached to the foot of the bed. This information is converted to an electrical signal which is recorded, amplified and printed out on paper for the doctors to study.

Using volunteer subjects with normal heart function, Dr. Smith and his associates, Dr. Thomas Shakespeare and Dr. Jack Reitan, postdoctoral fellows in anesthesiology, have used the BCG extensively to study the effects of drugs, particularly anesthetic agents, that depress heart function."

-more-

"We have also investigated drugs that raise the blood pressure," Dr. Smith noted. "Some drugs, using more conventional monitoring devices, may indicate on paper that they raise blood pressure, thus increasing the blood flow to vital organs of the body. Using the BCG we have found that in fact these drugs do not stimulate the heart to pump more blood, but instead raise the pressure by constricting the blood vessels and thus further decrease blood flow."

"A major advantage of the ballistocardiogram is that the studies on drugs and heart transplant rejection can be done with minimal risk and no pain or discomfort to the patient," Dr. Smith stresses. "The subject simply lies on the bed. There is no invasion into his body by a catheter or surgery which other studies of heart function often require."

In heart transplantation, the BCG is another valuable tool used to detect rejection. Coupled with other devices such as the electrocardiogram, which measures the electrical properties of the heart, by BCG, by measuring the mechanical function, is able to tell if the heart's pumping ability has been affected by rejection. This additional information aids the physicians to decide if rejection is or is not occurring and if treatment is effective.

"No single device can be relied upon," Dr. Smith says. "If the electrocardiogram voltage is low, possibly indicating rejection, but the BCG shows that the heart function is normal or improving, we would recommend that treatment of rejection is not advisable. We also have indications that the BCG may be more sensitive in detecting chronic rejection than the electrocardiogram."

"The principle of the BCG is not new, with crude uses of it reported in the late 1800's," Dr. Smith says. ."But all of its use until recently was a hit-and-miss proposition. It is only in the last several years, with the interest and input of engineers and physicists that the BCG has been refined into a precise science."

STANFORD -- The place and the times of the Lane Lectures being presented by Stanford University School of Medicine next week have changed. Originally slated for Cummings Art Building Auditorium, the lectures will now be held in Room M-106 of the Medical School.

Nobel Laureate George Wald, who is noted for his work on the biochemistry of vision, is now scheduled to give the lectures at 4:30 on Monday and Tuesday afternoons (March 30 and 31), and at 4:00 on Thursday afternoon (April 2).

Topics of the talks are: Monday - "The Molecular Basis of Visual Excitation," Tuesday - "Human Vision," and Thursday - "Ontogeny and Phylogeny at the Molecular Level."

The Lane Lectures were established by Dr. Levi Cooper Lane, one of the founders of the Medical School, in 1896. They are open to the public free of charge.

STANFORD -- Dr. Elliott Levinthal, 48, has been appointed associate dean for research affairs at the Stanford University School of Medicine.

"In his new position, Dr. Levinthal will assist the School in areas of nonmedical science and technology," said Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Medical School.

Included will be research activities that interface with other schools of the University--computer science, biomedical engineering, and health care systems studies. He will also be responsible for advising the dean on the planning of technological facilities and services that will have value to multiple departments within the Medical School.

Dr. Levinthal's deanship will be part-time. He will devote the remainder of his time to carrying on his present responsibilities as director of the Instrumentation Research Laboratory of the Department of Genetics.

Dr. Levinthal took the B.A. at Columbia University, 1942, and M.S. at Massachusetts Institute of Technology, 1943; then worked for Sperry Gyroscope. He received the Ph.D. at Stanford in nuclear physics, 1949. He was research director for Varian Associates, and formed his own company in 1953. Informal discussions with Dr. Joshua Lederberg led to his joining Stanford's Department of Genetics in 1961, broadening his field from electronics and physics into chemistry and biology.

STANFORD -- Dr. Lewis Aronow, associate professor of pharmacology at Stanford University School of Medicine, has been awarded an American Cancer Society--Eleanor Roosevelt International Cancer Fellowship.

The Fellowship was awarded to Dr. Aronow by the International Union Against Cancer and is supported by funds granted by the American Cancer Society to the UICC. The UICC is an international organization of cancer societies.

Dr. Aronow will take a sabbatical leave for a year, beginning in September, to study at the University of Cambridge, England. His research will concentrate on the understanding of the physical-chemical nature of the interaction of certain drugs with DNA (deoxyribonucleic acid), the core of living matter which determines heredity. It is related to the problem of cancer because some of the more effective anti-cancer agents are thought to act by effects on DNA.

Another research interest of Dr. Aronow's is the study of how steroid drugs combine with the protein molecules of a cell and regulate or inhibit the growth of the cell. For this research, Dr. Aronow was recently awarded an $11,000 grant by the California Division of the American Cancer Society.

Dr. Aronow joined the Stanford faculty in 1956 after receiving his Ph.D. in pharmacology from Harvard University. He received his B.S. degree (1950) from City College of New York and the M.S. degree in chemistry (1952) from Georgetown University.

STANFORD -- The final report and recommendations of the National Commission for the Study of Nursing and Nursing Education will be discussed at a regional conference March 26 at Stanford University.

Approximately 200 people involved in the delivery of health care in the Far West states of California, Oregon, Washington, Alaska and Hawaii are expected to attend. The conference will be held in Room 100 of the Physics Lecture Hall from 10 a.m. to 4 p.m.

Invited to participate in the conference are representatives of state governments and state nursing boards and associations, medical societies, hospital associations, health insurers, planning agencies, deans and directors of schools of nursing and directors of hospital nursing services in the Far West.

The National Commission for the Study of Nursing and Nursing Education is an independent corporation established in 1967 to implement the recommendations proposed in 1963 by the Surgeon General's Consultant Group in Nursing. Its work has been supported by grants from the Avalon and W. K. Kellogg foundations and by funds from an anonymous donor.

Editors: Story is released jointly by Burroughs Wellcome Fund of Tuckahoe, New York and Stanford University School of Medicine.

STANFORD -- Stanford University School of Medicine has received the Burroughs Wellcome Award in Clinical Pharmacology for 1970. This competitive Award of $125,000 has been made on behalf of Dr. Stanley N. Cohen to assist him and the Medical School to establish and develop a Division of Clinical Pharmacology. Dr. Cohen is the eighteenth Burroughs Wellcome Scholar in Clinical Pharmacology.

The Award from the Burroughs Wellcome Fund, Tuckahoe, New York, was announced today by William N. Creasy, president of the Fund, and Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine at Stanford.

"The purpose of the Burroughs Wellcome Clinical Pharmacology Award," Mr. Creasy said, "is to assist medical schools in setting up and developing programs where students can learn under a first-class scientist and teacher to apply scientific knowledge and techniques to the mechanism of action and proper therapeutic use of drugs."

The Burroughs Wellcome Fund is a nonprofit agency established in 1955 by Burroughs Wellcome & Co. (U.S.A.) Inc., a well known pharmaceutical company. In 1959 the directors of the Fund decided to support an annual competitive award in an effort to further teaching, training and research in clinical pharmacology. Since the Award's inception $1,950,000 has been awarded to eighteen medical schools in support of their developing sections of clinical pharmacology.

The clinical pharmacology program being developed at Stanford under Dr. Cohen's direction is a combined effort of the Departments of Medicine and Pharmacology. Among its major goals, Dr. Cohen explained, is "teaching a rational approach to drug therapy based on an understanding of the fundamental pharmacology of the drugs used. Such an approach requires consideration of the effects of disease on the action of drugs, since sicknesses themselves often affect the ways in which drugs work."

The teaching program will include lectures for students and house officers, postgraduate medical education conferences for practicing physicians, and a consultation service at Stanford University Hospital to deal with medical problems relating to the clinical use of drugs.

Areas of research in clinical pharmacology at Stanford will include investigation of the effects of environmental and genetic factors on drug metabolism, and of interactions between concomitantly administered drugs. A computer-based drug interaction program is currently being developed at Stanford which will alert physicians when undesirable drug combinations are being prescribed.

In addition, Dr. Cohen will continue his present research into mechanisms of resistance to antibiotics in infectious bacteria. Specifically, he and his associates have been studying the molecular nature of drug resistance and investigating methods of preventing drug-resistant populations of bacteria from arising.

-more-

Dr. Cohen is a graduate of Rutgers University and received his M.D. degree from the University of Pennsylvania in 1960. He served on the staff of the National Institutes of Health and was a member of the Department of Developmental Biology at the Albert Einstein College of Medicine prior to joining the medical faculty at Stanford in 1968. He is a recipient of a Research Career Development Award from the U.S. Public Health Service and is a member of the American Society of Biological Chemists, the American Society for Microbiology and other scientific organizations.

The medical scientists who become Burroughs Wellcome Scholars in Clinical Pharmacology are selected by a distinguished scientific advisory committee, composed of Dr. A. McGehee Harvey, chairman, professor of medicine at Johns Hopkins University of Medicine; Dr. Paul B. Beeson, Nuffield professor of clinical medicine, Oxford University; Dr. Julius H. Comroe, Jr., director of the Cardiovascular Research Institute at the University of California Medical Center, San Francisco; Dr. Alfred Gilman, professor of pharmacology, Albert Einstein College of Medicine; Dr. Carl V. Moore, Busch professor of medicine, Washington University, St. Louis, Missouri; and Dr. C. Gordon Zubrod, scientific director for chemotherapy, National Cancer Institute.

STANFORD -- A new concept of laser-light treatment has been used successfully by Stanford Research Institute and Stanford University scientists to treat eye diseases that can result in blindness.

Research carried on at the Stanford Research Institute in Menlo Park, the Stanford University School of Medicine, and the Palo Alto Medical Clinic showed that the intense, blue-green light of the argon gas laser is particularly suited for the treatment of certain eye diseases, because it is absorbed by the red blood pigment.

Laser stands for Light Amplification by Stimulated Emission of Radiation. Absorbed light turns into intense heat. The color of the argon laser is effectively absorbed by the blood in vessels of the eye. Thus diseases of vessels can now be treated with this laser.

Between June and December of last year, the Stanford researchers treated 176 eyes with the argon laser for 11 different eye diseases.

These were treatments for diseases of the retina, especially those occurring in diabetes, Eales' disease, in which eye blood vessels grow abnormally and bleed easily, sickle-cell disease which produces sludging of blood in peripheral eye vessels, and several congenital conditions.

"Treatment of some of these diseases has been considered futile in the past," said Dr. H. Christian Zweng, principal investigator and clinical associate professor of surgery in the Medical School.

"No general ill effects have occurred in any of the patients treated with this technique," Dr. Zweng added. The Stanford research was reported during the past year at several scientific meetings and in technical journals.

"While investigation to assess the advantages of the technique must continue, our experiences to date suggest that certain eye diseases are best treated early by argon laser photocoagulation," Dr. Zweng commented.

The work was initiated by a $246,000 grant and is continuing under a $165,000 grant from the National Institutes of Health to the Stanford medical school and Stanford Research Institute. The Medical School provides the medical experts while Stanford Research Institute contributes the physics and engineering talents in this interdisciplinary work. Medical collaborators include Dr. Hunter L. Little, clinical assistant professor of surgery, and Dr. Robert R. Peabody, clinical instructor in surgery.

Project leader at Stanford Research Institute is Dr. Arthur Vassiliadis. The team includes Norman Peppers, Dr. Richard C. Honey, Miss Ann H. Hammond, and Lloyd Alterton.

The photocoagulation instrument was designed, constructed, and tested at Stanford Research Institute.

-more-

The instrument makes use of a slit lamp by means of which the laser light is projected into the eye. Errors of refraction are reduced by a contact lens, through which the light is passed and brought into focus on the retina. The instrument offers an excellent illumination, three-dimensional viewing and high magnification so that the laser light can be aimed accurately at the lesion sites.

Power levels and the time of exposure are adjustable, and there is also a safety feature that gives warning if the aiming beam becomes too bright. The instrument also permits the taking of stereoscopic photographs of the eye.

An earlier method of light treatment, using a ruby laser, has been used by ophthalmologists for the past seven years to prevent detachment of the retina.

The ruby laser proved its value in treating retinal detachment, and it has also been effective in treatment of certain eye diseases. However, because of its red color it is not very effective in treatment of vascular diseases, Dr. Zweng said.

The effectiveness of photocoagulation or light treatment from any light source depends on the absorption of the light by pigmented tissue. In the process of absorption, the light energy is changed into heat energy, and a thermal effect, a burn, is produced.

Laser treatment, according to Dr. Zweng, has been used in ophthalmology for several clinical purposes: to prevent retinal detachment, to coagulate abnormal blood vessels, and to burn a hole in the iris of the eye when disease has closed the pupil or optical opening.

Instruments for light treatment have included the conventional photocoagulator which uses a high-pressure zenon gas tube as a source of white light. The instrument is bulky, must remain in a fixed position when in use, produces large scars compared to the pinpoint lesions produced by the laser, and introduces much energy into the eye.

Since conventional photocoagulators demonstrated both problems and dangers, ophthalmologists have been interested in exploring possible applications of the laser light in their field.

Before applying the new technique in humans, Dr. Zweng and his associates studied its use on Rhesus monkeys and rabbits in extensive experiments carried on at Stanford Research Institute. From these studies they determined the energy levels that could be used safely on patients, and evaluated the effectiveness of the argon laser in vessel interactions.

A model of Stanford's argon-laser photocoagulator is currently being displayed as part of a scientific exhibit at the Smithsonian Institution in Washington, D.C.

Picture page attached.

Dr. H. Christian Zweng of Stanford University School of Medicine aims beam of intense light from argon gas laser into the eye of patient being treated for a disease of the retina. The technical assistant is Miss Ann Hammond of the Stanford Research Institute in Menlo Park. The concept of using the blue-green light of the argon gas laser was developed jointly by scientists at Stanford University School of Medicine and Stanford Research Institute. It represents an advance over ruby lasers because the blue-green light it emits is absorbed by the red blood pigment. March, 1970.

Editors: The Stanford University School of Medicine and the Santa Clara County Public Health Department will hold a joint press conference Wednesday, March 11, 1970 to announce the establishment of a methadone treatment program for heroin addicts in Santa Clara County. Available to answer questions will be Robert Campos and Dr. Kenneth Meinhardt of the Santa Clara County Health Department, and Dr. Avram Goldstein of Stanford University. The press conference will be in Room 147 (Multipurpose Room) of the Mental Health Center, Santa Clara County Health Department, 645 South Bascom Avenue, San Jose, at 9:30 a.m.

(ADVANCE) FOR PM RELEASE WEDNESDAY, MARCH 11, 1970

SAN JOSE -- The Santa Clara County Public Health Department and the Stanford University School of Medicine have joined forces to bring several hundred heroin addicts into a new program in which methadone is used to treat narcotics addiction.

The drug, methadone, is said to end the addict's craving for heroin and other opiates and to block their effects, if he takes them. It does this without creating the sense of euphoria, the addict's "high", that interferes with normal functioning.

A joint statement by Dr. Elwyn W. Turner, director of the Santa Clara County Health Department, and Dr. Avram Goldstein, professor and chairman of the department of pharmacology at Stanford, said:

"On the basis of present research findings about methadone, we thought it would be well to initiate such a program in Santa Clara County.

"We estimate there are more than 500 addicts in the County and the number is growing. We have been personally disenchanted with the usual methods of treating heroin addiction. This is the first program that has come along that makes any sense to us in terms of objective measures of success."

New York's five-year methadone program, pioneered by Dr. Vincent P. Dole, has claimed to have treated addicts with 83 per cent success. Oregon reports to have gotten almost all its 400 addicts off heroin by using the chemical methadone as a substitute. Chicago's program has been equally rewarding in terms of salvaging human lives and reducing costly crimes.

Drs. Turner and Goldstein stressed that initially Santa Clara County's methadone program would have to grow slowly to permit controlled studies into several aspects of the drug. The long-term goal, however, is to extend methadone treatment to all heroin addicts in the County.

California law restricts methadone to research only. A bill by Assemblyman John Vasconcellos (D-Santa Clara) would remove those limitations and authorize full use under control of local health authorities. In addition to Santa Clara County, the only other programs presently approved in Northern California are in San Francisco and in Tulare County.

-more-

The new program will be under the administrative direction of Robert Campos, coordinator of the Drug Abuse Clinic of the Santa Clara County Health Department. Dr. Don Lowe, a psychiatrist, will be interim medical director, and Dr. Goldstein will direct the research aspects of the program. Others include Dr. Michael F. Cohen, a clinical psychologist; Mrs. Marian Morgan, psychiatric nurse; Miss Rosalie Adam, a public health nurse; Serapio Ortiz and Jose Espinoza, public servic aides.

A citizen's advisory committee, representing a broad spectrum of the San Jose community and the County, will guide methadone program operations. Included on the 35-member panel are representatives of the Mexican-American community, city and police, physicians, lawyers, clergymen, businessmen, educators, and two state assemblymen.

The program is not suitable for persons addicted to drugs other than opiates, Campos explained. It is not for young people who have been experimenting with drugs of the sedative-hypnotic type such as barbiturates and minor tranquilizers. These persons can be rehabilitated by other programs since they may not yet be addicted.

Twelve addicts are now being treated under the program which got its start in January, Campos disclosed. Each morning on the way to work, they stop at the Drug Abuse Clinic at 2320 Moorpark Avenue in San Jose, and take a carefully measured dose of methadone diluted in fruit juice. Addicts, selected at random, give urine samples for analysis to check if they are taking heroin at the same time.

"Even though these addicts have been under methadone treatment for a short time, their desire for heroin has simply dissipated," Campos and Dr. Goldstein stated.

Three of the addicts, interviewed at the Clinic, apparently agree that methadone is the answer to their problem.

"I can live a decent life taking methadone or I can live like an animal taking heroin," said a 40-year-old salesman and father of two. He said he was often forced to steal to feed his $100-a-day habit.

A 37-year-old warehouse worker and father of three children said he entered the program because "I wanted to feel normal again so that I could go to work." After three weeks of methadone treatment, his craving for heroin vanished, he added.

"I feel really good for the first time in my life," was the comment of a 38-year-old San Jose woman who has taken heroin since she was 19. She said she has not been "on dope" since beginning methadone treatments. And she recently refused to "have another fix" when tempted by a company of addict friends.

Dr. Goldstein said that Santa Clara County's program will emphasize research in aspects of methadone treatment and heroin addiction that are presently poorly understood.

"I do not feel that everyone in California should jump onto the methadone bandwagon and set up programs that may not be of the best kind," he said.

Some aspects of treatment to be studied include: methadone dosage levels, blood studies to determine differences in drug metabolism among addicts, and how methadone interacts when taken in conjunction with other medication. Other studies will focus on the effects of group psychotherapy and vocational rehabilitation of addicts in the methadone program.

-more-

"We are unquestionably dealing with some biochemical need in the brain for narcotic drugs," Dr. Goldstein explained. "How some individuals develop this need--whether it is self-induced or was present before the person turned to drugs--remains one of the fundamental questions about heroin addiction."

But methadone presents a problem. It is itself habit-forming--meaning that the user may have to rely on it for life. Asked to comment on this point, often used as an argument by critics of methadone programs, Campos and Dr. Goldstein replied:

"We look at drug addiction as a disease, similar in some respects to diabetes. If you have a diabetic on insulin every day for the rest of his life, would it ever occur to someone to say that he is bad because he is hooked on insulin?

"Insulin is a respectable drug for treating a disease that we understand, and no one considers it immoral."

Dr. Goldstein said that to a pharmacologist "there is no such thing as moral and immoral molecules. These chemicals are just drugs that do certain things," he said. "The worst thing about heroin addiction has to do with the consequences of its use.

"Since heroin is so expensive, addicts turn to crime to pay for their drug abuse. Thus, if the methadone experiment proves successful, the crime rate will be lowered, too."

He pointed out that methadone, which is pharmacologically different from heroin, is long-lasting, stable, can be taken by mouth, and costs only a few cents a day per patient.

STANFORD -- Parents of Children with Neurological Defects will meet at 7:30 p.m., Tuesday, March 10 in Room A335 of Stanford University Medical Center. Rose Grobstein, acting chief pediatrics social worker at Stanford University Hospital, will moderate a program on "The Effect of the Handicapped Child in the Home."

Children of parents in this group were born with myelomeningocele and in some cases hydrocephalus. The group welcomes new members and is eager to make itself available to other Bay Area parents in the same situation.

Parents who cannot attend the meeting, but would like information about the group may call Mrs. Roger Cummings at 258-6788 in San Jose.

STANFORD -- A new laboratory for rapid and accurate diagnosis of virus infections has been established at Stanford University Hospital.

The diagnostic virology laboratory, designed to work with state facilities in Berkeley, is able to provide service for numerous hospitals, clinics and physicians in the Bay Area. The State public health facilities will be used as a back-up for the Stanford laboratory, confirming certain test results and assisting with processing that cannot be done here.

"It will no longer be necessary for Stanford and other local medical facilities to send all specimens to Berkeley for the diagnosis of a particular viral infection," says Dr. Thomas C. Merigan, associate professor of medicine and director of the laboratory. "We will now have many test results in 24 hours and thus be able to select and begin proper treatment of the infection sooner. This will be a direct benefit to patients."

"The accuracy of the test results will also be improved," Dr. Merigan says. "Viruses are quite fragile. Previously we have had to freeze all samples and ship them to Berkeley, increasing the possibility that the viruses might be damaged or completely destroyed and thus distort test results."

The initial focus of the laboratory will be on those viruses which cause severe infections and diseases such as viral hepatitis, rubella (German measles), shingles, which attack nerves, and encephalitis, an inflammation of the brain. The scope of the laboratory will be expanded later to include viral infections which attack children such as mumps and polio, as well as those which attack the respiratory system.

"The prevention and cure of viral infections has been difficult," according to Dr. Merigan. "The opening of this special facility indicates the importance and scientific progress that has been made in understanding these microorganisms."

"We know that a virus replicates by infecting a healthy cell. The mechanism of virus growth within cells is similar to the cell's own growth mechanism. Therefore, it is very difficult to find selective drug treatments, which will attack only the virus and not the cell itself."

"The most common approach to fighting viral diseases has been immunization which has been highly successful against diseases such as smallpox, measles, and polio," Dr. Merigan points out. However, this approach does not work with all viruses. Certain newer antiviral drugs are under clinical investigation and as treatment becomes available, the rapid and exact diagnosis of viral diseases which our laboratory can provide will become increasingly important."

"It is our hope that a concentrated attack on viral diseases in our new laboratory will not only be of great value to patients throughout the community, but will also provide us with important data for continuing research into the understanding and prevention of viral infections," Dr. Merigan says.

Associated with Dr. Merigan in supervising the new facility is Dr. William S. Robinson, assistant professor of medicine. Two medical technologists, Dorothy Conklin and Mary Butera, are staffing the laboratory.

STANFORD -- Stanford University today announced it has received a gift of approximately 100 acres of land on the Monterey Peninsula.

The gift, made to the University by N. J. D'Ambrogio of Carmel, will be used to create a fitting memorial to his daughter, Maureen, who died of cancer in Berkeley on March 8, 1967.

The Maureen Lyles D'Ambrogio Memorial Fund will maintain a professorship in the Stanford University School of Medicine to be known as the Maureen Lyles D'Ambrogio Professorship, according to Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School.

The Professorship will be held by a faculty member engaged in cancer research.

The property donated to Stanford is known as Kent Manor. It overlooks the Pacific Ocean, on Highway 1, about three miles south of Carmel. Local publications have described it "as a choice spot located in the heart of California's most scenic coastal areas."

The estate was named after John H. Kent, executive vice-president and treasurer of the Eastman-Kodak Company during the early part of the century. His daughter, Ada Howe Kent, lived on the estate for many years with Margaret Kilpatrick, a life-long friend and companion.

When D'Ambrogio bought the property in 1950, it was part of the estate of Admiral Kenneth Kilpatrick, Mrs. Kilpatrick's son.

Mr. and Mrs. D'Ambrogio are keeping the residential compound of Kent Manor which consists of approximately 3 acres. Sometime later, D'Ambrogio said, he hopes that proceeds from this portion will form the basis for establishing a Medical Scholarship Fund at Stanford as a memorial to Mary L. Lyles of Flushing, Long Island, New York.

Miss Lyles, principal of the Murray Hill School in the early 1900's, was the only person who took an interest in D'Ambrogio when he was a boy of ten, after the death of his father.

D'Ambrogio is a Stanford University alumnus of the Class of 1917. Following his graduation and a brief academic career, he entered the field of financial consulting and became an authority on sugar production and consumption.

STANFORD -- Dr. Paul Berg has been appointed chairman of the department of biochemistry at the Stanford University School of Medicine.

He succeeds Dr. Arthur Kornberg, professor of biochemistry, who resigned as department chairman last year to return to full-time teaching and research.

Dr. Berg, 44, came to Stanford as associate professor in 1959 from Washington University School of Medicine in St. Louis, Mo., where he held a similar post. He became professor of biochemistry at Stanford in 1960.

In 1964 he was named California Scientist of the Year by the California Museum of Science and Industry for work concerned with decoding the genetic messages or patterns which determine how living cells make proteins.

Presently, Dr. Berg is engaged in research in how viral genes alter the growth properties of a cell and make it cancerous.

A native of New York City, Dr. Berg obtained the B.S. degree from Pennsylvania State University in 1948, the Ph.D. degree from Western Reserve University in 1952, and his postdoctoral training at the Institute of Cytophysiology in Copenhagen and at Washington University.

Dr. Berg's academic career is replete with honors. In 1959, he received the Eli Lilly Award in biochemistry. He was elected to the National Academy of Sciences and the American Academy of Arts and Sciences in 1966. Last year he received the Henry J. Kaiser Award for excellence in teaching.

Dr. Berg with his wife Mildred and son John live at 838 Santa Fe Avenue on the Stanford campus.

ADVANCE FOR P.M. RELEASE MONDAY, APRIL 27, 1970

STANFORD -- Dr. A. Dale Kaiser, professor of biochemistry at Stanford University School of Medicine has been awarded the U.S. Steel Foundation Award in Molecular Biology by the National Academy of Sciences.

The award, which was presented at the Academy's annual meeting today in Washington, D.C., cited Dr. Kaiser's "outstanding contributions in the field of bacterial viral genetics." It is presented for a recent notable discovery in molecular biology by a young scientist.

Dr. Kaiser and his colleagues have discovered that DNA (deoxyribonucleic acid) from a particular virus that attacks bacteria can infect susceptible bacterial cells and reproduce itself. This finding opened the way to a correlative analysis between the genetic and chemical structures on the DNA molecule. DNA is the material that controls heredity.

His research was supported by the National Institutes of Health and the National Science Foundation.

Dr. Kaiser received the B.S. degree in 1950 from Purdue University and a Ph.D. degree in Biology in 1954 from the California Institute of Technology. He joined the Stanford faculty in 1959.

STANFORD -- Dr. John A. Sbarbaro, medical coordinator of the Denver Neighborhood Health Program, will speak on "Community Health in the Political Arena," at 4 p.m. Friday at a health colloquium at Stanford University School of Medicine. He is sponsored by the Department of Community and Preventive Medicine and the local chapter of the Student American Medical Association.

Health care, its availability, accessibility and quality, has become an increasingly political issue. The speaker, who is noted for developing an entirely new system of health care delivery for a major American city, will discuss the involvement of government in the delivery of personalized health services.

The talk, in Room M-114 of the Medical School, is open to the public.

Violence

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

STANFORD -- Violence can be ended as soon as Americans realize that, for the first time in history, they are the masters of their own evolution, according to a study published by the committee on violence of the Stanford University School of Medicine.

The study, conducted by the Department of Psychiatry, says that Americans are panicked into destructive actions because they change conditions necessary for their survival much faster than they can adapt to the changes they make.

The Stanford committee builds its case on adaptation theory, arguing that much of man's behavior can be explained as a struggle to adapt to his environment.

Man lives in a technological era, but his true mentality is still that of a nomadic hunter who had to use violence for survival. This is no longer necessary, the committee says, because the nature of human adaptation has changed. The threats now facing man are more social, cultural, and psychological than physical.

In a short time, man's energies produced an unprecedented age of technology, and the old, slow evolutionary process--the behavioral and biological fit between the species and the environment--is out of balance.

"Our primitive forms of aggression, our violence, bellicosity and inclination to fight in a time of emergency increasingly work against our survival," the committee explains. Under today's different stresses those old tools of aggression that our ancestors used are not always adaptive.

"Thus America's current violence threatens our existence, not because we are more violent than ever before--but because violence makes it difficult for us to cope with our changing world," the committee states.

The committee's conclusions are offered in a 451-page book, VIOLENCE AND THE STRUGGLE FOR EXISTENCE, just published by Little-Brown and Company, Boston. The book is edited by Drs. David N. Daniels, Marshall F. Gilula and Frank Ochberg who were instrumental in forming a 23-member committee on violence after the assassination of Sen. Robert F. Kennedy to study aggression and its roots. The book includes chapters on the biological, psychodynamic, cybernetic and environmental bases of violence; effects of mass media on violence, assassination, gun legislation, the relationship of mental illness to violence, collective violence by minority groups, and the relationship of drugs to violence.

Conceding that there may be positive functions to violence--it may, for example, dramatize grievances and bring them to public attention--the committee warns current advocates of the politics of violence that violent methods tend to overwhelm the end for which they are employed. "Collective violence is, first of all, a polarizing tactic that...increases hostility and suspicion among groups. Once employed the possibility of restraint or reconciliation is considerably reduced.

"Finally, as violent behaviors are practiced, they become learned, and increasingly relied upon.... Thus the most unfortunate repercussion of violence is the continuation of the violent process itself."

-more-

The committee report calls for "a moratorium on violence" so that destructive energy can be channeled into more constructive solutions, and offers this message of hope:

. Violence is not an inherited trait. It can be understood and controlled.

. Man can now, for the first time in history, take charge of his own evolution. His destiny need not be imposed from without. Once man performs the revolutionary, but simple act of deciding that he can truly change, the era of violence can be ended.

To bridge the evolutionary gap, to adapt to their own age, and survive, the committee report insists that Americans must now alter their behavior as individuals and as a society. Americans must learn how to handle change fast. They must learn how to control evolution.

"We have marvelous adaptive abilities for coping with varying, even extreme situations," the committee says.

From the Stanford report here are specific proposals for individual action to change American society into an "adaptive" system:

. Stop being inconsistent about standards of behavior surrounding violence. A society that condemns some forms of violence but encourages others--war, capital punishment, and other collectively sanctioned violent behaviors--is breeding confusion.

. Learn about the potential hazards of overpopulation and its contribution to violent behavior, consider the merits of family planning, and limit the size of American families.

. Eliminate excessively punitive discipline for children and substitute nonviolent discipline and positive rewards. Parents who punish children by violent means teach them violence.

. Urge schools to develop curricula in the nonviolent resolution of conflict. Most books present the past as a procession of wars. Are students guided to draw the appropriate conclusions from the facts? Is their meaning for the present isolated and elaborated?

. Write to professions in the mass media urging them to emphasize that violence is destructive rather than glamorous, and to sponsor educational programs that teach nonviolent means for solving problems.

. Open channels of communication among members of different groups having different views and needs.

. Encourage legislators to enact strong firearms control laws and to establish a more effective legal machinery for the expression of grievances.

. Urge legislators, law enforcement officials, and judges to eliminate cruel social controls and penalties and to emphasize rehabilitation.

The Stanford report says "these recommendations are only a portion of the possible individual actions that can and must be taken. The essential point is that individual citizens are not helpless to act--each of us can take part in decreasing violence."

The future safety of the human species lies not so much on conserving old values as in learning how to hook onto the currents of change and ride them, the committee says. Americans must get serious about studying how change happens, to welcome it, to be stimulated by it instead of becoming terrified. The report sums up:

"Our outmoded adaptive behavior--our violent aggression keeps us from doing so. Our world has changed, yet we have not sufficiently changed with it, nor have we determined the shape of changes for tomorrow.

"If the gap between our behavior yesterday and the reality of today's demands grows too great, our continued dependence on violence may destroy us all, despite our great potential of being the masters, not the victims of our destiny."

Mailed April 21, 1970.

STANFORD--Television censors who eliminate the ugly consequences of violence from news and fictional presentations are doing more harm than good, according to a study published by a committee of psychiatrists at Stanford University School of Medicine.

Without its gory aspects, violence is depicted as a good, often quick way to get things done, says the committee on violence of the Department of Psychiatry.

"Ironically, the viewer is deprived of the one aspect of violence that might discourage violence," the committee states. "The censor cuts out the ugly consequences, the victim's pain and agony, and the wanton destruction of life.

"This restricts the viewer from determining the value of violent acts, since the full impact and range of consequences are not presented for appraisal."

The psychiatrists' findings appear in a new book, VIOLENCE AND THE STRUGGLE FOR EXISTENCE, published by Little-Brown and Co., Boston. The 451-page book is the result of an extensive examination of violence and its roots by the committee which was formed after the assassination of Sen. Robert F. Kennedy. The book, edited by Drs. David N. Daniels, Marshall F. Gilula, and Frank Ochberg, examines topics ranging from the biological, psychodynamic, and environmental bases of violence to relationships of violence to mental illness, drugs and lack of gun controls.

"Nowhere is violence as a sanctioned coping strategy more evident than in mass media portrayals of violence, especially on television," the psychiatrists write. "The media foster the image of the Violent American armed with gun, ignorance, and frustration, ruthlessly pursuing good and evil alike.

"Television, radio, and newspapers project a repetitive, staccato beat of violence, showing us that violence is valued, necessary, wanted, and even enjoyed."

One report cited by the Stanford psychiatrists indicates that a single television station showed 334 completed or attempted killings in one week. About 50 per cent of prime time programs feature violence and crime.

"The average American child from ages 3 through 16 spends more of his waking hours watching television than attending school. There is no question, no doubt whatever, of this constant flow of violent fare on TV and other media and its observation," the psychiatrists said.

What of the effect of this violent fare on viewers and readers?

"Although all mass media have appeal and impact, television has the most powerful impact," the psychiatrists said. "It effortlessly teaches pupils where they are, in the way humans learn best: through simultaneous presentations to the visual and auditory senses.

"For the young in particular learning involves observing, imitating, and then observing once again. Furthermore, television by virtue of its nearly real simulation of life, its inherent authenticity, blurs the line between reality and fantasy.

-more-

"The television industry knows this and so do advertisers. If TV can teach people to buy things, that is to alter their behavior, it also can teach people violence."

The psychiatrists show data suggesting a definite tendency for television programs to project content in which socially approved goals are most frequently achieved by methods that are not socially approved.

One study revealed that violence is used about one-third of the time as a means to various objectives. For programs most frequently watched by children, violence represented the solution 47 per cent of the time.

"Part of the tragedy is that television and mass media in general could be our most powerful tools for dealing with today's violence," the committee concludes. "Television could effectively promote adaptive alternatives to violence, and stress the many nonviolent ways to resolve conflict.

"It could encourage, if not induce, desired culture modification and intergroup understanding, but not while the lesson, the accepted cultural tradition, remains that violence, especially when disguised by the cloak of history, fantasy or rightness, is an effective, acceptable way to cope."

STANFORD -- Failures of American Medicine, in rural America and in the country's urban ghettos, will be the focus of Student Day at Stanford University School of Medicine, April 25.

An all-day program devoted to a single issue is an innovation. Traditionally, medical students have presented research papers and guest speakers have delivered talks on divergent topics. This year the students have moved the program from the Medical School to Bishop Auditorium in the Graduate School of Business so that more people can attend. It is open to the public.

"Our objective," says Chairman Les Cordes, "is simply to make Student Day 1970 more significant."

He has planned the program as a way of increasing understanding of problems on the current medical scene, and of solutions to those problems that are now being attempted.

"Most of us are aware in a general way of the lack of adequate health care in rural areas and city ghettos," he says, "but we may not have been exposed to specifics. Our speakers face the problems every day and are actually involved in large- and small-scale efforts to correct them".

Los Angeles health workers Mrs. Marion Grindell and Roy Evans will talk at the morning session, which begins at Bishop at 9:30.

Mrs. Grindell, who is on the Narcotics and Dangerous Drugs Commission in Los Angeles, will speak on "Failures of Health Services in the (south) Los Angeles Ghetto," the area which takes in Watts

Evans was addicted to drugs for seventeen years until he committed himself to rehabilitative training four years ago. His talk "Ghetto Psychology and Establishment Medicine" is based on his experiences working on several of Los Angeles' most active delinquency and drug abuse prevention projects since that time. Currently Evans is a district project coordinator in Narcotics Information in the L.A. Department of Community Services, and he is executive director of a project called Bridge Back, Inc.

The early afternoon's emphasis will be on the rural scene. Dr. Gerald Bassett, assistant professor of preventive medicine at the University of Washington and a 1959 Stanford medical alumnus, will talk about rural health in the State of Washington and other states.

-more-

John Hatch, M.S.W. and assistant professor of preventive medicine at Tufts University Medical School, will describe the Tufts-Delta Project at Mound Bayou, Mississippi. Started three years ago, the project is a working model of comprehensive health care in a rural district.

After these presentations, a panel of Stanford professors, resident physicians and medical students will discuss community health care from both a national and a local point of view. Panel members will be Dr. Count Gibson, Chairman of the Department of Community and Preventive Medicine at Stanford; Dr. Norton Kalishman, Stanford resident in pediatrics and a founder of the People's Medical Center; Miss Kate Lorig, training coordinator at the Alviso Community Service Organization Family Health Center; Don Williams, a first-year medical student who was instrumental in setting up the Black Man's Free Clinic in San Francisco; and Bob Korns, a third-year medical student who has served a clerkship at the Southern Monterey County Medical Group Rural Health Project, King City.

Dr. John Sbarbaro, director of the Denver Neighborhood Health Center, will conclude the Day's program with "Summary and Impressions."

Dr. Sbarbaro will also speak on the Stanford campus Friday, April 24, on "Community Health in the Political Arena" at a Health Colloquium at 4 p.m. in Room M114 of the Medical School.

STANFORD -- Dr. Abner M. Harvey, head of the Department of Medicine at Johns Hopkins School of Medicine, will discuss the health care system of a new model city on the East Coast on Saturday at Stanford University School of Medicine.

Dr. Harvey, the first Louis and Dorothy Kovitz Visiting Professor at Stanford, will speak at 9:30 a.m. in Room M-112 of the medical school. The meeting is open to the public.

He will discuss the planning and implementation of the Columbia Project, a new model retirement city being built halfway between Washington, D.C. and Baltimore, Md. Johns Hopkins School of Medicine is responsible for the health care system of the project.

Dr. Harvey will also participate in medical grand rounds at the Palo Alto Veterans Administration Hospital early Thursday morning and give the clinical pathologic conference at 11 a.m. Thursday in Room M-106 of the medical school.

Dr. Harvey received the A.B. (1930) and D.Sc. (1949) degrees from Washington and Lee University and the M.D. degree (1934) from Johns Hopkins. He has headed the department of medicine and served as physician-in-chief of Johns Hopkins Hospital since 1946.

The Louis and Dorothy Kovitz Visiting Professorship was established last year by Dr. and Mrs. Louis Kovitz of Los Altos.

FOR PM RELEASE TUESDAY, APRIL 14, 1970

ATLANTIC CITY -- Eczema, probably one of the most frequent skin disorders of medical significance, results in an estimated 8 million visits to physicians each year in the United States, with less than half that total to dermatologists.

Although women may comprise a majority of patients, the disorder is also common among men.

Despite the antiquity and extent of the disease, its cause is not fully understood and its therapy remains empiric. One authority on the subject has observed that he knows of no other chronic disease so capable of humbling the learned physician more than a stubborn skin eruption.

Eczema's symptoms are redness, itching, small blisters, and discharge from the skin of a fluid that tends to dry into scales and crusts. For many years physicians have suspected that eczema has an immunologic origin and may be caused by unknown agents either inside or outside the body.

A paper presented Tuesday at the 54th annual meeting of the Federation of American Societies r Experimental Biology in Atlantic City has given further basis to this belief.

A dermatologist, Dr. Jørgen Søndergaard of Denmark, working with Dr. Malcolm W. Greaves of University Department of Dermatology, Newcastle-upon-Tyne, England, reported that they had isolated an unknown pharmacological substance previously unrecognized in allergic contact eczema. Dr. Søndergaard is now doing related work as a research associate in histochemistry and dermatology at Stanford University School of Medicine.

Using a special perfusion method, which permits direct analysis of pharmacological substances released in inflamed skin, Drs. Søndergaard and Greaves found the substance in 21 of 30 patients with eczema, but failed to find it in 18 volunteers with normal skin.

Further studies in patients known to be susceptible to immediate-type reactions -- insect bites or drugs -- failed to produce the chemical agent.

The substance, tentatively identified as a smooth muscle-contracting agent (SMCA) has turned out to be a fatty acid that can be easily extracted with organic solvents, the investigators said.

Dr. Søndergaard said that work is now under way in Dr. Greaves' laboratory in England to define the chemical composition of the SMCA substance suspected to be related to agents called prostaglandins. The other possibility is that the substance may turn out to be an entirely new agent.

Once identified, the SMCA agent could be injected in the skin of volunteers to see if it would produce eczema, Dr. Søndergaard explained.

He added it is quite likely that the SMCA substance is one of many complex chemical mediators which cause skin eruption. Identifying these and finding ways to block their action could hopefully lead to control of eczema.

54th ANNUAL MEETING

SUBJECT..... "Recovery of a Pharmacologically Active Fatty Acid from Human Allergic Contact Eczema Using a Skin Perfusion Method"

AUTHORS..... Jørgen Søndergaard, M.D.;
Malcolm W. Greaves, M.D., Ph.D., M.R.C.P., University Department of Dermatology, Newcastle upon Tyne 1, England;
Research Associate, Stanford University School of Medicine, Department of Pathology, Division of Histochemistry, Stanford, California 94305.

TIME..... 9:00 a.m., Tuesday, April 14, 1970

PLACE..... Room 13, Convention Hall Hotel, Atlantic City, New Jersey

PROGRAM..... Immunopharmacology

CONVENTION
ADDRESS..... Dennis Hotel RELEASE TIME April 14, p.m.

***

Histamine, bradykinin, 5-hydroxytryptamine and the prostaglandins are known to be highly vasoactive in human skin but direct evidence that these agents participate in human allergic contact eczema is lacking. A method of continuous in vivo perfusion with warm Tyrode solution has been developed which permits direct analysis of pharmacological agents released in inflamed human skin. Using this method a pharmacological substance (SMCA), previously unrecognized in allergic contact eczema has been recovered. This substance, obtained from eczematous skin in 21 of 30 patients was neither due to histamine, kinins, 5-hydroxytryptamine nor acetyl choline. Its solubility in ethyl acetate at pH 3 indicates that it is a fatty acid of the prostaglandin type. Histamine was found in 7. Kinin activity was recovered in 12 of the 30 subjects, but these results did not differ significantly from those obtained in the normal skin of 18 control subjects. No histamine, 5-hydroxytryptamine or SMCA was found in the control group.

Both perfusion and assay techniques have been described by us in detail in an earlier paper. Two wide-bore needles with 8 holes perforated along the shaft were inserted immediately subdermally in parallel 10 mm apart in opposite directions along the flexor aspect of the forearm. Warm sterile Tyrode solution was infused through one needle and recovered through the other into siliconised glass tubes in an ice packed fraction collector. Recovery was assisted by confining the area of perfusion with elastic bands and by applying gentle suction with a peristaltic pump. Perfusate was collected in successive 15 min aliquots. Histamine was assayed biologically against the atropinised guinea pig ileum, its presence being confirmed using the specific antagonist pyrilamine. Kinin activity was assayed by using the oestrus rat uterus and rat duodenum mounted in a single organ bath. 5-hydroxytryptamine was assayed fluorometrically.

Allergic contact eczema is a form of sustained inflammation due to cell-mediated delayed hypersensitivity. A group of 30 patients with contact eczema was studied. Fourteen were allergic to nickel, five to chromate, three to rubber, two to primula, two to cobalt and one each to formalin, colophony, neomycin and benzocaine. These patients had only minor skin involvement at the time of investigation, and the arms were clinically unaffected in all cases. Patch tests 6 cm^2 area were applied to the flexor surface of the forearm and perfusion of duration 90 minutes was carried out on the inflamed skin 48 hours later.

-more-

Eighteen control subjects were studied. These were patients with localized non-inflammatory lesions such as naevi, virus warts, alopecia and neoplasms. Univolved skin was perfused in each case. In two of these who had negative patch tests to nickel, a 6 cm^2 patch test was applied to the forearm and perfusion of the underlying skin was carried out 48 hours later. No histamine was found in the 18 subjects during perfusion varying in duration from 15 to 90 minutes. Kinin activity was detected in 6 subjects. This was of low concentration ranging from 0.1-4 ng/ml. No hydroxytryptamine or SMCA was detected in any of the experiments.

In 21 of the 30 patients with contact eczema an unidentified smooth muscle-contracting agent (SMCA) was found. This was an agent which contracted the guinea pig ileum, but was not histamine, 5-hydroxytryptamine or acetyl choline, since it was not inhibited by the corresponding competitive antagonists. It was not a kinin, since although it contracted the rat uterus, it also contracted the rat duodenum, whereas kinins relax the duodenum.

Of the 30 patients, histamine was found in only 7, kinin in 12 and 5-hydroxytryptamine not at all. However, the possibility that these agents may be regularly released in contact eczema is not excluded. Failure to recover them may be due to rapid degradation, dilution by the Tyrode solution or depletion by tissue diffusion.

Experiments designed to characterize SMCA are at present incomplete. The activity is clearly not due to Slow Reacting Substance (SRS-A) since SRS-A does not contract the rat uterus. A Lymph Node Permeability Factor has been recovered from lesions of contact dermatitis in the guinea pig, but it is inactive against the guinea pig ileum and rat uterus.

Prostaglandins are widely distributed among human tissues and are highly vasoactive in human skin. The possibility that prostaglandin-like fatty acids may be responsible for the smooth muscle-contracting activity in perfusates obtained from contact dermatitis in the present study was raised by the following observations. Perfusates from four patients with contact dermatitis which contained the unknown substance were extracted by partition between ethyl acetate and water at pH 3. In each case the activity was found in the ethyl acetate fraction since after evaporation the redissolved residue would contract the guinea pig colon and rat uterus, whereas the waterphase contained no activity. The response of the isolated rat uterus and duodenum to extracted SMCA and extracted standard prostaglandin E_1 were then compared. Both extracted SMCA and extracted prostaglandin E_1 gave a biphasic response with the rat uterus and a contraction of the duodenum.

Since pharmacological activity resembling SMCA has recently been detected by us in inflammation due to ultraviolet radiation, using a similar method, but not in short-lived whealing inflammatory reactions the possibility arises that this activity may be a characteristic of human sustained inflammation in general.

STANFORD -- "Code 66"

Those ominous words, meaning "cardiac arrest," are not unfamiliar to employees of Stanford University Medical Center. But when they echoed down the halls on the morning of April 1, something was different. This arrest was not in a patient room but out in front of the Medical Center near the outpatient clinics.

It began shortly before 9 a.m. when Mr. and Mrs. Jesse Wing of Salinas, late for Mrs. Wing's clinic appointment, dashed from a parking lot toward the main entrance. Suddenly Mr. Wing collapsed.

A man walking out a door saw Mr. Wing fall and notified Mary Gall, medical center coordinator. "I knew by looking at him that he hadn't just fallen and was not going to get up," Mrs. Gall remembers. She sent word out to Mrs. Wing that help was on the way and then ran to the medical clinic where she found Dr. David Clark, a postdoctoral fellow in cardiology.

"All I said was 'STAT', a man has fallen in front of the clinics,' and Dr. Clark was on his way," Mrs. Gall says. While he began external cardiac massage, and mouth-to-mouth resuscitation, Mrs. Gall took Mrs. Wing inside, put a "Code 66" on the public address system, and told Barbara Gamberg, orthopedic clinic nurse, to get an emergency tray and gurney.

The response was immediate from all corners of the Medical Center--inhalation therapy, emergency room, nursing service, security, anesthesiology. From that moment on, everything was clockwork.

Mr. Wing, 71, was placed on a gurney and quickly transported across the front of the Medical Center to the elevator and emergency room. Riding the gurney and straddling Mr. Wing was Dr. James Rushing, an intern in medicine. He never missed a stroke of cardiac massage. Dr. Dennis Fung, a resident in anesthesiology, ran along side, providing ventilation with a resuscitation bag.

Once in the emergency room, an electrocardiogram showed that Mr. Wing was in ventricular fibrillation, when the large chambers of the heart lose their rhythmic pumping action. Electric shock and other medications were given to stabilize his heart beat and he was shortly taken to the Coronary Care Unit. By noon, Mr. Wing's EKG was stable and he was sitting up and talking with CCU personnel. Today he is on the road to recovery.

There is little doubt but that the fast work by Dr. Clark and the efficient, rapid response to the "Code 66" in the crucial minutes after Mr. Wing collapsed, did save his life. As his wife said, "If it was going to happen, we could not have been in a better place."

STANFORD -- Dr. Howard B. Kirtland of San Diego is the new president of the Stanford Medical Alumni Association, and Dr. George J. Laird of Burlingame is the new president-elect.

Dr. Kirtland, a surgeon, succeeds Dr. Larry E. Heiges, Jr. of Lompoc. He will serve as president of the Association through June, 1971.

The new president, who received his M.D. degree from Stanford in 1944, also serves on the clinical faculty of the University of California at San Diego Medical School and is a consultant in vascular surgery at the U.S. Naval Hospital in San Diego. He is also a member of the board of directors of the Comprehensive Health Planning Association for San Diego and the Imperial Valley counties. Dr. Kirtland is also chairman of the committee for continuing education of physicians, under the Area VII California Regional Medical Programs.

Dr. Laird, a general surgeon, received his M.D. degree from Stanford in 1940.

Elected for three-year terms on the board of governors of the Association were Dr. Henry F. Davis, '62, Carson City, Nevada; Dr. James A. Clever, '62, Tiburon; and Dr. John M. Palmer, '60, Davis. Dr. Charles D. Miller, '47, Redding, and Dr. George V. Webster, '37, Pasadena, were re-elected for three-year terms. Secretary-treasurer of the Association is Dr. David A. Rytand, '33, Atherton, Bloomfield professor of medicine at Stanford.

STANFORD -- Seven weeks ago, Cecil Upshaw, ace relief pitcher for the Atlanta Braves, thought his baseball career had come to an end. Today, physicians at Stanford University Medical Center are optimistic that Upshaw may be back in the bullpen by the end of the season.

April 8th started out as a "great day in sunny California," Upshaw recalls, with the Braves emerging victorious over the San Diego Padres. It ended as a nightmare.

Walking back to the hotel with two teammates, Upshaw jumped into the air, demonstrating a basketball shot he made in college. Unexpectedly his college classring on his right hand hooked on a metal awning ; shearing off the soft tissue and severing the two small arteries of his finger.

"At first, I thought it wasn't very serious," Upshaw says. But after a doctor in San Diego examined the injury, Upshaw was told that the finger might have to be amputated. The doctor recommended examination and treatment by hand specialists at Stanford University.

"I was ready to do anything," the six foot six inch pitcher recalls. "All that kept going through my mind was that the years of training and work, since I was a kid, through near starvation in the minor leagues and finally to the major leagues, were going to go down the drain."

Surgeons at Stanford reconnected one of the severed arteries of Upshaw's finger on the morning of April 9 after he was flown by chartered plane from San Diego to Palo Alto. Subsequently, he received daily treatments to augment the supply of blood and oxygen to the injury through the tiny blood vessels of the finger.

"They watched and waited and so did I," Upshaw says. "Each day I'd look at the blackened finger tip and try to prepare myself for the worst. On the other hand, if the doctors just smiled at me, I'd become optimistic.

Today Upshaw's finger has normal coloring and doctors have said that the finger will be retained. Presently Upshaw is undergoing skin grafting to close the finger's wounds and physical therapy to restore finger motion.

-more-

Cecil Upshaw

222

"If it's a question of mind over matter, I'm going to be at least throwing a baseball by the end of the season," Upshaw says. Last year he had the second best relief pitching record in the National League with 27 saves, six wins and only four losses.

Upshaw has been playing baseball as long as he can remember. He was first approached by a big league scout at the age of 13. Two years later he was voted the most valuable player at a national baseball tournament sponsored by the Veterans of Foreign Wars.

"I was a 'whiz kid' then because I was bigger and more coordinated than most kids my age," Upshaw says. "After that the others caught up with me and I really had to learn to pitch."

While attending Centenary College in his hometown of Shreveport, La., where he graduated in 1965, Upshaw was approached with contracts from all but one of the teams of both the National and American Leagues. He signed with the Braves, then of Milwaukee, in 1964.

During the off season, Upshaw works on the business staff of an Atlanta minor league team in Shreveport, coaches a 7th grade basketball team, and writes a sports column for the Shreveport Times. He and his wife, Jeannie, have two children, Cecil III, 3, and a daughter, Carole, 6.

STANFORD -- The staff and students of Stanford University Medical Center today closed their seventh annual art show, one which drew 206 entries, the second largest number since the show was first staged in 1964.

The artwork, exhibited in the Hospital for 10 days, was awarded 29 prizes and 17 honorable mentions from a panel of professional judges, and a special "Most Popular" award determined by personnel at the Center.

One of the most unusual entries to receive a blue ribbon from the judges was a felt and velvet vest made by Bonnie Weil of Palo Alto. Miss Weil, an administrative assistant at the Center, works extensively in the medium she calls "stuffware" designing and creating pillows as well as wearing apparel.

Thomas Hohn of Menlo Park, a postdoctoral fellow in biochemistry, won a first award for an unusual black and white photograph of a bleak mountain swirled in snow. Dr. Abraham M. Gottlieb, who was a winner in the oils category last year, won a first award this year for a nostalgic watercolor called "Sand and Shadows." Dr. Gottlieb resides in Menlo Park, is director of the Palo Alto Veterans Administration Hospital.

Dr. Raymond Stofer of Woodside, research associate in surgery, won a blue ribbon for a metal sculpture, "My Thing." Dr. Stofer's sculptures consistently impress judges--he has won six times in the seven-year history of the show.

Other top winners were: nurse Marilyn Landgraf of Palo Alto for an untitled abstract acrylic; Flora Noel of Palo Alto, lab technician in biochemistry, for her oil "Washoe Valley;" nurse Doris Sandiford of Palo Alto for her lilting color photo "Flying a Kite;" Darrell Tank of Sunnyvale, orderly at Stanford University Hospital, for a pencil drawing "Portrait of a Boy;" fourth-year medical student Anne Osborn for a batik wall hanging trimmed in orange fringe; and substitute nurse Helen Delkos of Palo Alto for "Madonna," a decoupage.

The popular vote went to Ras Donald Bel, III, for his oil "Find the Little Lamb with Two Horns."

Chairman of the show was Phyllis Marrion of Palo Alto, a secretary at Stanford University Hospital. Judges were June Bangham of Palo Alto, Gil Clark of Stanford's Escondido Village, Gordon Holler of Los Altos, Doris Hoover of Palo Alto, and Dr. Robert Kantor of Atherton.

STANFORD -- A new centralized monitoring console is keeping simultaneous watch over eight patients at one time in the cardiac surveillance unit at Stanford University Hospital.

All 28 beds of the unit are equipped with monitoring capabilities. Any eight of the beds can be connected to the main console in the nursing station at one time.

"The installation of this equipment provides us with increased flexibility," according to Dr. Alfred Spivack, director of the coronary care unit at the Hospital. "Patients who need monitoring, particularly in an emergency situation, will no longer have to be moved from regular beds to those with bedside monitoring equipment."

The new console has 16 channels to monitor the electrocardiograms of eight patients plus one additional psysiologic measurement such as the blood pressure. The electrocardiograms are displayed visually on an oscilloscope at the nursing station. An alarm system automatically alerts nurses to any irregularity in the patient's heart beat. When the alarm system is triggered, the console immediately begins a printout on paper of the EKG for study by the doctors.

Another feature of the new equipment is a tape recording system where physicians can record observations and treatment for later review and evaluation.

Funds for the new equipment were donated by a $20,000 gift from the Stanford University Medical Center Auxiliary.

"The new equipment on this unit is a logical extension of the smaller, coronary care unit adjacent to it where patients require more intensive treatment," Dr. Spivack says. "It is also consistent with our philosophy of a graded care system, based on what the patient needs to make a smooth and gradual transition back to normal life."

-more-

Monitoring Console

222

The average patient stay in the Coronary Care Unit is five days. Most have been stricken with a heart attack, heart block, rheumatic heart disease or severe heart failure of other causes, all which can require intensive observation and possible emergency resuscitation. Once a patient's condition has been stabilized, he can be moved to the cardiac surveillance area.

"The fact that a patient is moved from the Coronary Care Unit does not mean that it is the end of his heart problem," Dr. Spivack says. "In the surveillance unit, there is a program of gradual and continuing healing and phasing back into normal activity."

An important feature of the cardiac rehabilitation program is a regimen of exercises designed to prevent loss of a patient's cardiovascular reflexes. The tone of blood vessels is often lost during prolonged bed rest. The exercises are organized and prescribed so that specific muscles are utilized, yet do not require the patient to expend any more energy than he would by simply rolling over in bed.

Nurses play an important role on the cardiac surveillance area. They are instrumental in the rehabilitation and education of both the patient and his family by helping them to understand the nature of the heart disease and to cope with the emotional stresses of the disorder.

Members of the house staff at the Hospital, in conjunction with the Division of Cardiology, provide continuing care on a 24-hour basis in the cardiac surveillance area.

STANFORD -- Stanford University School of Medicine today announced the establishment of an endowed professorship in the Department of Pediatrics in honor of Dr. Harold K. Faber, emeritus professor and head of the department of pediatrics at Stanford for 26 years before his retirement in 1949.

Announcement of the endowed chair was made by Dr. Robert J. Glaser, vice president for medical affairs and dean of the School of Medicine, during dedication ceremonies of the Dr. Harold K. Faber Auditorium at the Stanford Children's Convalescent Hospital in Palo Alto. Dr. Faber served as medical director of the Hospital from 1919 until 1956.

"Dr. Faber's contribution to pediatrics at Stanford, and in a broader sense, to world pediatrics, are without equal," Dr. Glaser said. "The honor implied by an endowed professorship in his name is one which he richly deserves."

Dr. Faber is internationally known for his polio research as well as for his teaching and clinical skills. He is a former president of the American Pediatric Society and received the Society's Howland Medal and Award in 1956 for his extensive contributions to his profession.

After acquiring an A.B. degree (1906) from Harvard and an M.D. degree (1911) from the University of Michigan, Dr. Faber joined the Stanford faculty in 1915 as an assistant professor of pediatrics. At that time, pediatrics was a division of the department of medicine. After 18 months in the Army Medical Corps in 1918-19, he returned to Stanford as an associate professor and head of the division of pediatrics. Dr. Faber was appointed as a Professor of Pediatrics in 1923, and in 1927 succeeded in having Pediatrics made a separate department of the Medical School.

Dr. Faber and his wife reside in San Francisco.

Transmitted on Business Wire 5/21/70

STANFORD -- A medical education task force, headed by Associate Dean Bernard W. Nelson of Stanford University School of Medicine, today proposed a series of steps through which the number of students from America's minority groups in medical degree programs could be increased from the present 2.8 per cent to 12 per cent by 1975.

The report, released by the Association of American Medical Colleges in Washington, D.C., is an analysis and a series of recommendations made by the task force to an Association committee representing physicians, hospitals, minority groups, and medical colleges.

Dr. John A. D. Cooper, president of the AAMC, said: "This analysis shows how and where we have failed to attract or to keep in the medical education system those minority students who are fully qualified to become physicians. It gives us some new information to help us with the critical problem of choice--how to select wisely from among qualified applicants."

The report sets the following targets for minority student representation in medical school:

Academic Year	#of Minority Studens Entering Medical School	% Minority Students of Total Students
1970 - 71	660	3.9%
1971 - 72	1,000	5.3
1972 - 73	1,200	7.1
1973 - 74	1,400	8.9
1974 - 75	1,600	10.6
1975 - 76	1,800	11.9

Principal conclusions of the report are:

. the most important factors in retention of students during premedical education are the availability of financial aid at the college level and the student's perception if its availability at the medical school level.

. the main barrier today for minority students in attending medical school is the inadequacy of financial aid. Coincident with increasing enrollment of minority students in medical schools, Federal government and other sources of funds have been decreasing.

. counseling should be directed to those efforts which will help the student to fully realize his potential and to gain the confidence needed to pursue a career in medicine.

. existing medical school class size represents the major obstacle for increased production of physicians with the result that many capable students are not permitted to study medicine. Increases in class sizes are needed.

-more-

Based on these conclusions, the task force has recommended a two-part financing program, a short-term solution being a single national organization which would act as a central coordinating body for the multiple sources of financial aid, and as a possible long-term solution, the task force endorsed the concept of an educational opportunity bank.

The latter would provide loans to all qualified medical students to enable them to finance completely their educational costs at the medical school of their choice, repayment to commence when the student enters his professional career, based on an agreed percentage of income.

The task force also recommended that a network of regional centers be established to provide factual and personal information about career opportunities for minority students in the health professions.

Another information source for prospective medical students would result from a recommended expansion of the AAMC Office for Minority Student Affairs.

The report emphasized that this will not be an action program until various institutions make decisions and go to work to make things happen.

"We need action and we will need funds," said Dr. Cooper. "This report is only a blueprint--it tells us how to build. We need more physicians in America and we need them to represent a democratic cross-section of the qualified persons in various parts of our society."

The study was financed by the Alfred P. Sloan Foundation and directed by Dr. Nelson. Working with him were representatives from AAMC's Washington Office, minority groups, and a dozen institutions engaged in education in the health professions. Consultants to the task force were Richard A. Bird and Gilbert M. Rodgers, graduate students in systems engineering at Stanford.

STANFORD -- A 50-year old man from Atherton became the 24th heart transplant patient today at Stanford University Hospital.

The recipient, Frank McMahon, 1 Lilac Dr., is in satisfactory condition. He received his new heart from an anonymous donor in a 4 1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

McMahon, a retired businessman, has suffered from heart disease for the past four years. He and his wife, Rita, have two children, Judy, 20, and Frank Jr., 22.

In addition to McMahon, Stanford has nine other surviving heart transplant patients, seven of whom have been discharged from the hospital to resume normal lives.

LIVINGSTON, CALIFORNIA -- Stirred into action by the knowledge that the city's only physician will soon be leaving, citizens of this small Merced County community Monday night endorsed a plan that would provide medical services to the people in the area in partnership with the Stanford University School of Medicine.

The plan, developed by a citizens committee representing a cross-section of Livingston's ethnic, social, and economic groups, was described at a meeting attended by 250 persons in Livingston High School Auditorium.

Under the proposal, two doctors would be serving Livingston with 24-hour medical care. Clinic facilities, now owned by Dr. J.J. Wolohan, Livingston's only family physician for more than 25 years, could be leased and operated by the community through a nonprofit corporation.

The physicians--a specialist in internal medicine and a pediatrician--would live in Livingston, and in addition to their clinical duties, will teach medical and nursing students and residents who will commute from Stanford to augment the Clinic staff. The physicians will be faculty members of the Medical School.

Staff appointments at the M.D. level will be made by the Clinic's board of directors from candidates acceptable to the Medical School for full-time faculty appointments. The board, composed of representatives from more than 20 local organizations, will guide Clinic operations and set policy.

The clinic will be self-supporting--it will charge fees for services rendered, according to Keith Winton, a local businessman and member of the committee that developed the proposal.

To help the project get started, Area III of the California Regional Medical Programs will provide funds for the developmental phase of the program. The local board plans to initiate a fund drive in Livingston to raise an additional $25,000 needed, Winton said.

Clinic operations are expected to begin in July, with assistance from Stanford faculty, and students. Dr. Wolohan, presently a resident in psychiatry at St. Mary's Hospital in San Francisco, will continue to commute to Livingston to see patients as long as the community remains without a doctor, according to Winton.

The community will assume responsibility for the Clinic September 1, and a committee will soon begin work on financial and legal aspects of the transition of the health clinic from a private to a community operation by a nonprofit corporation.

Dr. Count Gibson, professor and chairman of the Department of Community and Preventive Medicine, told the audience that the Livingston project will lead "to the kind of partnership that university medical centers have not thought of achieving in the past."

STANFORD -- Three Stanford University medical students were named Alumni Scholars during proceedings at Medical Alumni Day Saturday (May 16). Each received a scholarship award of $500.

Dr. Larry Heiges of Lompoc, president of the Stanford Medical Alumni Association, presented the awards to Robert Clark Aber of the fifth-year class; David K. Edwards, III, of the fourth-year class; and John M. Vierling of the third-year class.

They were chosen on the basis of high academic achievement, leadership, excellence of character and "promise of becoming a doctor who will render superior service to his fellow men."

Others who were honored by being chosen as candidates for the awards are: fifth-year students Douglas R. LaBreque and Bobbette K. Ranney; fourth-year students Layton F. Rikkers and Joel D. Ohlsen; and third-year students F. Wells Shoemaker, Jr., and Bruce M. Mermuth. As a recognition award, the candidates each received a copy of the newly published book A Stanford Heritage, by Dr. Gunther W. Nagel, emeritus professor of surgery and director of alumni relations at the School of Medicine.

The Alumni Scholars and their parents' names and addresses are listed below:

CALIFORNIA - Los Angeles: John M. Vierling, Dr. and Mrs. Lester H. Vierling, 439 Catalina Drive

- Van Nuys: David K. Edwards III, Mr. and Mrs. David K. Edwards II, 15235 Lorne Street

PENNSYLVANIA - Easton: Robert Clark Aber, Mr. and Mrs. Donald C. Aber, 32 North 17th Street

Stanford's longest surviving heart transplant patient, Robert O. McKee of Palo Alto, died last night at Stanford University Hospital. He was 52.

Death came at 5 p.m. Sunday, May 17. The cause of death is undetermined, pending an autopsy.

Mr. McKee, who was the world's second longest surviving heart transplant, received his new heart on Aug. 31, 1968. For the past 21 months, Mr. McKee had returned to work selling real estate, swimming, golfing, bowling and fishing, none of which he had been able to do in the three years preceding his transplant operation.

Mr. McKee is survived by two sons and a brother.

There are eight other surviving transplant patients at Stanford, seven of whom are discharged from the hospital and are leading normal lives.

STANFORD -- Distribution patterns of blood and air flow in the lungs, and how they influence the efficiency of breathing, will be studied by a Stanford University medical research team under a grant of $193,363 from the John A. Hartford Foundation of New York.

The purpose of the study is to discover how the distribution is normally regulated, and how it is disturbed in patients in acute respiratory distress.

The grant, the third from the Foundation to Stanford in support of research on respiratory problems, was announced today by the Foundation's president Harry B. George, and Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine at Stanford University.

The research will be directed by Dr. Grant Fletcher, associate professor of anesthesia.

"In the last few years we have learned to sustain breathing, in terms of volume of air intake, in patients with respiratory complications," Dr. Fletcher said. "But if the blood is not distributed to the same areas and in the same proportions as the air, the exchange of carbon dioxide and oxygen is inadequate. For instance, investigations in the Premature Research Center at Stanford have shown that in the respiratory distress syndrome in premature infants, abnormal blood flow in the lungs is one of the main contributing factors."

Many patients with lung disease develop severe heart disorders, particularly right-sided heart failure. The reverse is also true--many heart disease patients develop lung diseases, including pulmonary edema, which is accumulation of fluid in the lungs.

Dr. Fletcher's team will investigate the factors in blood and the lungs which combine to cause pulmonary edema, and why edema occurs in some patients and not in others who appear to be in like condition.

Dr. Eugene Robin, who is now at the University of Pittsburgh, will join the research team in July, coming to the University as professor of medicine and physiology. His excellent background in heart and lung diseases will be particularly valuable in the work under the new grant, Dr. Fletcher said.

Under previous grants his team has studied mechanical limitations of breathing due to surgery, chest injuries and other diseases; respiratory distress syndrome in premature infants; effects of drugs and certain metabolic diseases on the brain's respiratory center; and infections that frequently complicate low-level osygenation.

Hoover Pavilion - Psychiatric unit

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

STANFORD -- Stanford University Hospital today announced the opening of a new 20-bed psychiatric unit in the Herbert Hoover Pavilion, the hospital's annex on the corner of Palm Drive and El Camino Real.

The opening climaxes an eight-month, $328,000 renovation job of a 6,000 sq. ft. area on the ground floor, formerly housing laundry facilities, and an 8,000 sq. ft. outdoor patio and recreation area.

The new unit, which operates on the concept of an open Therapeutic Community, will free space in the main Medical Center for an additional 15 adult medical and surgical beds, according to Dr. Thomas A. Gonda, director of the hospital.

Dr. George D. Gulevich, assistant professor of psychiatry and director of the Therapeutic Community, said the "unit is designed to create an atmosphere that promotes a sense of community life in a homelike setting."

A lounge area, decorated with comfortable living room type furnishings, is the core of the unit with pleasant sleeping quarters around it.

Kitchen and laundry facilities, interview rooms, and group and occupational therapy areas are other improved features. A nicely landscaped patio area outside the unit provides a site for recreational activities.

"The Therapeutic Community is an open unit where a small group of people help each other learn, change and grow," Dr. Gulevich said. "It is designed, both in governing philosoply and physical facilities, as a small-scale representation of the society from which its members come with similar responsibilities and opportunities. In such a setting, many kinds of therapy can be undertaken and the doctor-patient relationship can be broadened."

The therapy program, Dr. Gulevich added, is short term and designed to help patients resume social living outside the hospital as soon as possible.

The unit was designed by Stone, Marraccini, and Patterson, and work was done by Welch Construction, Inc. of Menlo Park.

Hoover Pavilion, which houses the new psychiatric unit, has served thousands of Peninsulans for four decades. In 1965, it was remodeled by the City of Palo Alto at the cost of $1.3 million and reopened as part of the Palo Alto-Stanford Hospital, then jointly owned by the City and Stanford University. In 1968, the City sold its hospital holdings to the University, and Hoover Pavilion became part of the medical complex renamed Stanford University Medical Center.

Laundry facilities located on the ground floor of Hoover were phased out in Spring, 1968, when the Medical Center joined with other area hospitals and built a cooperative laundry facility in San Carlos.

STANFORD -- The executive committee of the Stanford University School of Medicine today issued a statement condemning what it termed as "violent and destructive acts against black people in this country."

The action, taken in the aftermath of two student killings on the campus of Jackson State College, Mississippi, was unprecedented for the 22-member committee which has never spoken out on a political issue as a group.

The committee consists of department chairmen of the School. A resolution passed by the committee read:

"On the basis of news reports it appears that the deaths of two black students and the wounding of 10 more at Jackson State College, Mississippi, last night is only the latest in a long history of violent and destructive acts against black people in this country.

"The white community experienced a little of such tactics in the tragic deaths of four Kent State students last week. However, the Jackson State deaths occurred not in the heat of a confrontation, but in a fusillade pumped into a dormitory. It recalls the massacre at Orangeburg State College, South Carolina, two years ago. We also learn today that the six black residents of Augusta, Georgia, killed two days ago, were all shot in the back.

"It is idle to demand that our country get out of Indochina as long as violent racism flourishes in this country. Therefore, we the members of the executive committee of the Stanford Medical School faculty, unanimously extend our profound sympathy to the black community and call upon the President of the United States and the Attorney General to take necessary steps for the protection of all our citizens and to compel the accountability and responsibility of all our law enforcement agencies."

STANFORD -- A 62-year old man from Menlo Park became the 22nd heart transplant patient last night at Stanford University Hospital.

The recipient is Eric Wainwright, 445 Oak Grove Ave. He received his new heart from an anonymous donor in a four and 1/2 hour operation performed by a team of surgeons headed by Dr. Edward Stinson. Wainwright is in satisfactory condition.

Wainwright who owns a janitorial service and manages the Monte Claire Apts. has suffered from serious heart disease for the past 8 months. He and his wife, Norah, have two grown children, Rodney who is a student in England, and Mrs. Ann Myers, who lives near Oxford, England, where her husband is stationed with the U.S. Air Force. The Wainwrights immigrated to the U.S. from England five years ago.

In addition to Wainwright, Stanford has eight other transplant patients who have been discharged from the hospital to resume normal lives.

STANFORD -- More than 450 practicing physicians from the Midpeninsula have added their voice to the growing number of citizens protesting America's involvement in Vietnam, and more particularly the new thrust into Cambodia.

Another 917 signatures "condemning the continuation and expansion of this tragic war" have been obtained from faculty members, students, and staff of the Stanford University Medical Center.

The statements against U.S. involvement in Southeast Asia are being initiated and circulated by the medical communications committee of the Stanford Medical Community for Peace.

Sixty per cent of the 450 signatures came from doctors outside the medical center, according to Dr. Robert E. Greenberg, and Dr. Naomi Remen, members of the medical communications committee.

STANFORD -- Stanford University medical students have received the endorsement of the governing board of the Santa Clara County Medical Society for working to present their anti-war sentiment through established political institutions.

The endorsement was in the form of a resolution passed by the council of the Medical Society Monday night. It said:

"The council of the Santa Clara Medical Society endorses the approach of the Stanford medical students and commends them on their commitment to pursue a nonviolent role in having their views presented and in working through the established political institutions to influence changes in this nation's policy."

The resolution praised the students "on being dedicated to interfere in no way with the operation of the Stanford Medical Center nor to compromise patient care."

"We urge others," said the council, "to support their approach since these students represent the previously uncommitted nonviolent majority of medical students who now hope to take and hold leadership from the militants and to pursue a constructive course."

Stanford medical students and faculty have organized the "Stanford Medical Community for Peace" to carry out a "rational dialogue between students and the community and convince the latter of the need for a change in national policy in Southeast Asia."

STANFORD -- Sen. George McGovern will go on prime time network television tonight to appeal for public support of a nonpartisan amendment that would cut all funds for the Indochinese war by June, the Senator's office announced today in Washington.

Gordon Weil, press secretary to McGovern, said the 30-minute program will be aired at 7:30 p.m. (PDT) on NBC-TV which sold the time to McGovern backers for $70,000. (The program will be on KRON-TV, Channel 4, San Francisco).

Appearing with McGovern will be Senators Mark Hatfield, Harold Hughes, Frank Church, and Charles Goodell.

Among supporters of the McGovern-Hatfield amendment is the Stanford Medical Community for Peace. The group created a special committee to affect a change in national policy by working through established democratic channels. According to Drs. Oleg Jardetzky and David Hogness, committee members, the group has been responsible for more than 3,000 letters mailed from the Palo Alto-Stanford area in favor of the McGovern-Hatfield amendment.

Professor Hogness who has been in close touch with Senator McGovern's office said today that the number of senators now co-sponsoring the amendment has risen from 8 to 21.

STANFORD -- Heart valve disease and its common clinical manifestations will be the topic of a day-long postgraduate symposium Friday, May 15, at Palo Alto Veterans Administration Hospital.

The symposium, open to interested physicians in the community, is sponsored by the Stanford University School of Medicine, Palo Alto VA Hospital, and Area III, California Regional Medical Programs. It will begin at 8:30 a.m.

Topics to be discussed during the meeting include physical signs of heart valve disease, interpretation of the electrocardiogram and other studies, and selection of patients for open heart surgery. During this program each participating physician will examine selected patients and review their laboratory data for discussion in the afternoon session.

Faculty members for the program include Drs. William Angell, assistant professor of surgery; William C. Fowkes, assistant professor of medicine; E. William Hancock, associate professor of medicine; Herbert N. Hultgren, professor of medicine; David Rytand, Arthur L. Bloomfield, professor of medicine; and Bernard Treister, instructor in medicine.

Dr. Richard P. Lewis of Ohio State University Medical School, Columbus, and Dr. James Pfeiffer of Pacific Medical Center, San Francisco, will take part as guest lecturers.

Lloyd Beam of Richmond, Calif., died Sunday morning at Stanford University Hospital while undergoing heart transplant surgery. He was 41.

Death came at 12:35 a.m. as a result of lung complications.

Beam, a retired businessman, had suffered from heart disease for the past 3 1/2 years. He is survived by his wife, Jane, and his mother, Mrs. Orua Beam, Sacramento.

Beam was Stanford's 21st heart transplant recipient. Eight other patients who have received new hearts have been discharged from the hospital to resume normal lives.

STANFORD -- A rumor verification center has been established at Stanford University under the sponsorship of the committee on violence of the Department of Psychiatry.

Purpose of the nonpartisan center is to track down rumors throughout the Stanford and Palo Alto area and determine if they are true or not. It is staffed by volunteers representing faculty, staff, and students.

Citizens, who are concerned about a rumor, should call 329-0220 any time, day or night. Incoming calls are logged on a data sheet and then attempts are made to validate, confirm, or negate them through cooperating agencies and field workers, and independent agencies.

The center was established because of the tense situation that has prevailed on the campus during the week, in the hope of preventing future violent incidents caused by false rumors.

Mary M. Griffith 415: 321-5310

STANFORD -- An ad hoc group of minority employees at Stanford University Medical Center today renounced the war in Southeast Asia as hypocrisy and said they "support all efforts" to end it.

The group, called "Minority Employees of the Stanford Medical Center," issued the following statement:

"Be it resolved that because of the racist and imperialistic war in Southeast Asia, and because of the exploitation of the poor and minorities in this country, we renounce the hypocrisy of the government with regard to the aforementioned issues and support all efforts to terminate this hypocrisy."

Stanford medical center faculty, students, and staff have in the past week redirected many of the regular activities of the Medical School to efforts to end the war in Vietnam. This is the first time minority employees have spoken out as a group on the issue..

Minority members make up approximately one-fourth of the Medical Center's 3,000 total employees.

STANFORD -- The concern of the medical community and many segments of society is the resolution of the war in Southeast Asia, a Stanford medical educator said Friday.

"Once that is achieved, it will be possible for us to redirect the resources of the nation to correct the other ills that beset our society," said Dr. Robert J. Glaser, vice-president for medical affairs and dean of the Stanford University School of Medicine.

"Until we decrease the huge committment of our resources to the military, we cannot deal effectively with the health needs of our fellow citizens," he continued. "We cannot provide educational opportunities for all, we cannot revitilize our cities, and we cannot make social justice a meaningful concept for all people."

Dr. Glaser made his remarks at a convocation of about 800 medical students, faculty, and staff at the Medical School courtyard. The convocation was organized by the Stanford Medical Community for Peace.

He said the war was extended precipitously, at a time when "we were led to expect its early termination. We must now find a rational way to bring about a change in national policy.

"We can be encouraged by what has taken place here at the Medical Center. We also gain strength from the efforts of colleagues in other Universities which are making their views known to Congress and the executive branch."

Dr. Glaser said he is pleased by the degree of cooperation among faculty, students, and staff, and the direction of their activities.

"But, he added, "we have certain responsibilities. All segments of our community are agreed that patient care in the Hospital and the Clinics must go forward without interruption, in order to fullfill our obligations to patients.

"Communications between the faculty, staff, and students must be frequent and to be effective must utilize established channels. Of particular importance is the need to provide accurate information. Great caution must be exercised to insure that rumors and misinformation are not spread.

"Working together we have the best opportunity for success in seeking the goal to peace."

During the past week, members of the Stanford medical community organized groups to protest the war and to work to effect its ending. Many classes were cancelled and some were held with small attendance. Medical School activities related to patient care were not affected.

STANFORD -- The faculty senate of the Stanford University School of Medicine passed a resolution at a noon meeting today condemning President Nixon's action as unwise, immoral and harmful.

"The decision of President Nixon on April 30, 1970 to commit American ground combat forces to action on Cambodian territory is deeply exacerbating the distrust of Stanford students and faculty in the U.S. government," the resoltuion read.

It continued: "Therefore, we 1) condemn President Nixon's action as unwise, immoral and harmful; 2) urge the use of every legal means to resist the implementation of this decision; and 3) commit ourselves to pursuing non-violent means of rescinding this decision."

In other action, the faculty senate resolved that "As teachers, physicians and research workers dedicated to the preservation of human life and the amelioration of human suffering, we wish to register our grave concern about the growing evidence of deepening dissension and mounting acts of past violence both on our campus and in and beyond our nation, which are obviously interrelated.

"We deplore the use of violent means to register protest on this campus and deplore the escalation of the war in Indochina recently manifested by the invasion of Combodia. We urge that everyone in the Stanford Medical Community work in a constructive and peaceful manner towards the solution of both our immediate and underlying problems."

The two resolutions of the faculty senate have been disseminated to the representative governing faculty badies of all American medical schools, to the Stanford Medical Community for Peace, the chairman of the Stanford Academis Senate and to all faculty members of the medical school.

The senate action was unprecedented because some senators believe the faculty body should be apolitical. Tuesday the senate met but was unable to agree on an appropriate response to the situation in Cambodia.

STANFORD -- Stanford medical school faculty, staff and students are organizing action groups to persuade community leaders and others of the need for a change in U.S. government policy in Southeast Asia.

The ad hoc group of 350 members Monday night voted to support the general University-wide strike so that classroom activities and other functions of the Medical School could be redirected to this educational effort.

The group, called "Stanford Community for Peace," issued a statement Wednesday morning arguing that its "action is taken out of a profound concern for all humanity, and with the expressed intent not to disrupt health care and necessary research activities of the Stanford Medical Center.

"We want to emphasize to the community that the strike does not mean that the medical school is 'shut down.' Insofar as the University is the rational dialogue between students and faculty, we insist that the University is now more open than ever before."

The group said it is organizing the large number of concerned faculty, staff and students into specific action groups to convince the community of the need to change the government's policy in Southeast Asia.

The group plans to provide speakers, organize panel discussions, "and other activities to present our views in greater detail, and to provoke a hopefully productive discussion and democratic action."

In other developments, members of the Stanford Nursing School faculty and students sent telegrams to local and state representatives at the annual American Nursing Association Convention in Miami, Florida, urging that they support a resolution in opposition to the conflict in Southeast Asia, and the violence that has occurred in past weeks in the United States.

The group is also circulating petitions against the war among nurses of the Stanford and El Camino Hospitals.

Another group of students, faculty and staff has formed a national strike committee to spread the idea of a national general strike through cooperation with labor organizations, teachers and others.

The medical students have set up a "nerve center" in the Medical School building to coordinate their activities, press relations, and publications.

STANFORD -- Doctors must take a serious interest in political and social questions--including the Vietnam war--because their lives are increasingly in danger of becoming "a mere mockery," a noted Stanford University cancer researcher said Monday night.

Speaking before a convocation of 1,000 persons in the Stanford Medical School courtyard, Dr. Henry S. Kaplan cited what he termed "the ultimate irony of the position of the physician today--more people killed in Vietnam in one week than he would hope to cure in a lifetime."

Dr. Kaplan is chairman of the Department of Radiology in the School. In 1969 he received the Atoms for Peace Prize for his contributions to cancer research, including work on Hodgkin's disease, a cancer of the lymphoid tissues.

He reminded his audience that 40 years ago, the five-year survival rate for patients with Hodgkin's disease was 12 per cent. Largely as a consequence of work at Stanford the five-year survival rate today is 73 per cent.

"In another era that would have been the most heartening achievement," Dr. Kaplan commented. 'A man would have been proud of it and feel a sense of accomplishment.

"And yet today I am confronted with the irony that more prople are being killed in Vietnam in a week than I can ever hope to save in a lifetime."

He said that one of the many contributions of pediatricians in recent years was the reduction in infant mortality in this nation and less advanced countries in the world.

"They succeeded in eradicating infant mortality in these nations but population increases have far more wiped out the social gains," he said.

Although pediatricians introduced their treatments because they were humanitarian, they have been criticized by social scientists as "being blunderers and ignorant individuals" tampering with something they did not understand, according to Dr. Kaplan.

"Today the population explosion is upon us," he said. "We as doctors who are concerned about saving lives are increasingly being forced to wonder whether our actions in so doing are not actually anti-social. This is an ironic twist, indeed."

He said that many physicians are facing with an increasing sense of despair the knowledge that in ghettos there are health problems, poor sanitation, malnutrition, and other social conditions.

"These problems are preventing even the most rudimentary application of things we knew about medicine 25 years ago," Dr. Kaplan said.

He added: "These are few of the reasons why I feel a sense of irrelevance-- a sense that we as physicians are not able to contribute through our life's work that which we had hoped to contribute.

-more-

Dr. Kaplan
222 May 5, 1970

"We feel increasingly that our entire lives are being made meaningless by all that is transpiring around us and it is for this reason that physicians, medical students, and staff must take a serious, continuing, and meaningful interest in political and social questions in the world that surrounds us.

"Because without political involvement on our part, our entire lives today are increasingly in danger of becoming a mere mockery."

Dr. Kaplan's talk was preceded by other speakers who condemned the Vietnam war and the government policy to expand the war into Cambodia.

Dr. Robert B. Textor, professor of education and anthropology, who lived in Southeast Asia for several years, said that he "sees no reason for President Nixon's gamble to succeed."

Citing that four years ago, on May 4, he held his first Stanford "teach-in" on Vietnam, Dr. Textor explained; "At that point we thought we could win. There was light at the end of the tunnel. The years went by, the bombs were dropped, and today there is no more hope of winning a military solution than there was then."

He added there is a need for citizens to be reasonably informed on the issues surrounding Vietnam and to make their views known to their congressmen who can deny the military of necessary funds.

Other speakers included Banning Garrett, political science graduate student from Brandeis University, Alan Strain, senior counselor in the office of the Dean of Students, and Dr. Robert Chase, professor and chairman of the Department of Surgery.

The convocation in the Medical School, organized by students to discuss Cambodia and its implications, was peaceful. Later in the evening, an ad hoc group of students, faculty and others passed a resolution to work for a general strike to emphasize their concern over events in Southeast Asia.

In addition, the resolution called for educational efforts to reach the public and government for the purpose of changing U.S. policy in Southeast Asia. The statement said that Medical School activities related to the care of patients or those considered necessary by each individual will not be affected.

Tuesday's classes in the Medical School were held as usual, with 25 per cent attendance.

STANFORD/A Black who spent 17 years of his life in crime and dope addiction offered some insights on confrontation when he addressed the gathering at Stanford Medical Student Day recently.

Roy Evans, who volunteered himself for rehabilitative treatment four years ago and who is now district coordinator for the Narcotics Information Service in the Los Angeles Department of Community Services, says he does not advise anyone without experience to "confront the Establishment cold bloodedly."

He told his audience: "Don't waste your energies, your ammunition. Try to utilize it where it will do the most good and be the most effective."

Throughout his talk, Evans referred to attitude change as the only effective way to bring about changes in the community.

Evans scored those who "jump up and march all the way down to city hall, and don't accomplish anything.

"Whitey just doesn't play the game. Whitey just sits back and listens. Soon we are all on our way back to Watts talking about 'Boy, didn't I tell'em!'"

"We have the same thing with students," Evans went on. "Breaking out windows, knocking down doors, taking old buildings and in the final analysis we have, in a very small and immature way, flexed our muscles.

"Confrontation, in my opinion, takes experience. There are qualified, experienced people that you can get to sit down with you and help you begin to learn to confront each other first... they can also help you learn how to confront the faculty...and help the administration learn how to confront you," he recommended in a not-too-explicit reference to encounter therapy.

"They are as afraid of you as you are of them," he said. "Where fear exists, we have to be concerned -- (or) it can easily develop into an explosive kind of a situation, where nobody wins."

-more-

Ironically, Evans' remarks on Medical Student Day were coming near the close of one of the most turbulent months in Stanford's history.

Attitude change can come when people do not feel threatened, when people feel they can let their hair down, he said.

He found fault with the basic beliefs he says now form the foundations for attitudes in our society, saying, "most of us today are deeply committed to the symbols of authority, achievement or affluence. This is our basic commitment and yet, intellectually or consciously, we know that these are not the most important things in the world. But how do we operate? This is something that we have to look at -- Now!

"I'm not concerned with trying to convince you about what is happening in the ghetto, about what is being done to poor us, so to speak. I am much more concerned that you look at what is being done to you."

Evans pointed out that our present family system is a "poor and shattering one," based on the quest for food, clothing and shelter. "For me," he said, "That is a false sense of motivation. It is not the basic kind--it is still something that is motivating an individual from outside himself. I am saying that now that we have reached a point where this is no longer a primary concern, we must build motivation from within."

"I am a firm believer, Evans said, "that what you are doing to you is very much related to what you're doing to me, and if you get yourself together, then I don't have to worry about how you are going to treat me."

STANFORD -- Medical alumni of Stanford University will hold their annual meeting and reunion at the School of Medicine Saturday May 16.

Scientific programs will be held throughout the morning and during part of the afternoon. Dr. Gunther W. Nagel, director of alumni relations for the School, will preside over the morning session "Surgical Correction of Disability."

In the afternoon, president of the Medical Alumni Association Dr. Larry Heiges, Jr. of Lompoc will preside over the Association's short annual meeting.

The afternoon sessions will be held on "Anesthesia, Clinical Physiology and Clinical Pharmacology," and "Anesthesia and Biomedical Engineering," moderated by Drs. John P. Bunker, professor and chairman of the Department of Anesthesia, and J. Weldon Bellville, professor of anesthesia, respectively.

At the end of the afternoon a representative of the medical student body will discuss anti-war protest activities in the Medical School.

STANFORD UNIVERSITY NEWS SERVICE, STANFORD, CALIFORNIA 94305

FOR INFORMATION CONTACT: Bob Beyers, 321-2300, ext. 2558

FOR IMMEDIATE RELEASE

STANFORD--By majority vote, Stanford trustees have decided to abstain from voting the University's proxies on proposals to expand the General Motors board of directors and to create a shareholders committee for corporate responsibility.

The University owns about 24,000 shares of GM stock. The two proposals were advanced by associates of Ralph Nader.

On all other issues before the May 22 GM shareholders meeting, the Stanford proxy will, in keeping with general practice, be given to GM management.

The trustee action was based on a report and recommendations from an ad hoc committee created by the board last month. The report noted that: "According to past policy the Stanford Board would give to management the proxy covering the University's General Motors stock, including the power to vote on the Project of Corporate Responsibility proposals.

"However, the trustees note the strong Stanford student and faculty views on these proposals, and recognize the sincerity with which they are held. Indeed, trustees individually share the view that our society needs to take more effective steps to protect our environment by assuring both cleaner air and clearer water.

"The proposals present new problems to institutional stockholders. In the urgent press of events at Stanford during the past several weeks, the current ad hoc committee has been unable to investigate and consider adequately the issues involved in these new problems."

Headed by Ernest C. Arbuckle, former Business School dean and chairman of Wells Fargo Bank, the committee included: W. Parmer Fuller, president of the Board of Trustees and vice president of PPG Industries; Fred H. Merrill, chairman of Fireman's Fund American Insurance Company; Prof. G. L. Bach of the Stanford Graduate School of Business, nationally prominent business economist; and Robert Grant, member of the Associated Students Council of Presidents. Bach and Grant are both members of the Trustee Committee on Finance.

In late April, students voting in a campus referendum supported both of the so-called Nader proxy proposals by margins of about 5-to-1. The vote to expand the board of directors was 3,849 to 786 among 10,000 students, while the support for the shareholders committee was 3,967 to 786.

According to The Chronicle of Higher Education, an independent weekly, the University of Pennsylvania has given the chairman of its investment committee "authority and discretion" to vote their 29,000 share proxy for the Nader proposals, but did not bind him to support these measures.

Antioch College, which owns 1,000 shares, is expected to support the proposals. Governing boards which have rejected the proposals include the Universities of California (100,000 shares), Michigan (29,000 shares) and Texas (66,000 shares). Institutions still studying their position include MIT (291,000 shares). Harvard (287,000 shares) and Yale (86,000 shares).

Because of conditions on campus, the Stanford trustee meeting was held in San Francisco this month. About 20 demonstrators supporting the student strike appeared in the hallway outside the board offices. They were met by University Relations Director Lyle Nelson and Controller Kenneth D. Creighton, who indicated the board heard student views through students on its committees but that individual trustees might talk with them after the meeting. Several did so. ####

Stanford heart transplant patient Eric Wainwright, 445 Oak Grove Avenue, Menlo Park, died this morning at Stanford University Hospital.

Mr. Wainwright, 62, died at 4:50 a.m. The cause of death is undetermined pending an autopsy.

Mr. Wainwright received a heart transplant on May 13. He is survived by his wife, Norah, and two grown children.

Stanford has 9 other surviving heart transplant patients, 7 of whom have been discharged from the hospital to resume normal lives.

STANFORD -- An increase in daily service rates beginning Wednesday, July 1, was announced today by Stanford University Hospital.

The daily rates, approved Monday (June 22) by the hospital board of directors, will be increased $4.50 for ward and $5 for semi-private community medical and surgical patients.

The new basic rates are: ward, $61; semi-private, $66.50; and private, $75.

"The continuing rise in the cost of materials and employee compensation has made an increase in operating revenues necessary," according to Dr. Thomas A. Gonda, director of the hospital. "We are vigorously involved in programs aimed at developing operating and administrative innovations which can help to slow the hospital-cost spiral."

He pointed out that the $5.50 average increase in daily rates announced today is less than the $7.50 average increase necessary last year.

Dr. Gonda said that the hospital is also attempting to reduce the time a patient spends in the hospital, and in some cases this will help offset some of the impact of the rate increase. He said that the pre-admission testing program which began at the hospital last year was initiated as a move to reduce the length of hospitalization. This program enables certain patients to complete their medical tests at the hospital as outpatients before being admitted.

STANFORD -- The School of Medical Technology at Stanford University Hospital last night (June 25) graduated its fourth class of medical technologists.

A full year of training in the clinical laboratory and the classroom has prepared the class of ten for licensure by the State, and for certification by the Registry of the Medical Technologists of the American Society of Clinical Pathologists (ASCP).

The new technologists will work in laboratories in hospitals, clinics, and medical research firms. Their specialized training includes instruction in ten fields, with emphasis on biochemistry, hematology and microbiology.

On July 1, the school will accept a new twelve-member class. Entrants must have a bachelor's degree. Most have majored in biology, chemistry or microbiology.

Dr. Paul L. Wolf is director of the School of Medical Technology, and Miss Lisa von der Muehll is teaching supervisor.

The 1970 graduates are:

Miss Donna Jean Brunni, a 1969 graduate of Washington State University, daughter of Mr. and Mrs. Donald Brunni, Route 6, Box 6336, Bainbridge Island, Washington.

Miss Cynthea Ann Chan, a 1969 graduate of the University of California at Berkeley, daughter of Mr. and Mrs. Sun Chan, 584-46th Avenue, San Francisco, California.

Miss Dee Evans, a 1969 graduate of San Jose State College, daughter of Mrs. Maralyn Evans, 415 South Murphy, Sunnyvale, California.

Mrs. Mary Kathryn French, a 1969 graduate of California State Polytechnic College, wife of Mr. Jim French and daughter of Dr. and Mrs. Laverne Bucy, 115 La Entrada, San Luis Obispo, California.

Miss Carol Glenn, a 1969 graduate of the University of New Mexico, daughter of Mr. and Mrs. Rolland Glenn, 1416 Tomasita St., Albuquerque, New Mexico.

Mrs. Mary Ann Cheung Ho, a 1966 graduate of Dominican College, the wife of Mr. Yuan Ho, 3102 David Avenue, Palo Alto, and daughter of Mr. and Mrs. Philip Cheung, 1125 Balclutha St., Foster City, California.

Miss Lorraine Ishizu, a 1969 graduate of the University of California, Berkeley, the daughter of Mr. and Mrs. Tatsuo Ishizu, 8313 Josard Road, San Gabriel, California.

Mrs. Carolyn Ann Iskra Olds, a 1967 graduate of Humboldt State College, the wife of Mr. DuWayne Olds, 475 - 24th St., Arcata, and the daughter of Mrs. Holly Ann Iskra, 1336 B St., Arcata, California.

Mr. James Thangels, a 1969 graduate of California State College, Hayward, the husband of Mrs. Carol Thangels of Menlo Park, and son of Mr. and Mrs. James Thangels, 70 Amherst, Oakland, California.

Miss Alexa Schindler, a 1969 graduate of the University of California at Davis, the daughter of Mr. and Mrs. Arnold Schindler, 3322 Freeman Rd., Walnut Creek, California.

STANFORD -- Members of organized labor and of the University community will join in an all-day symposium to discuss domestic problems resulting from the war in Indochina this Saturday (June 27) on the campus.

The symposium, which is co-sponsored by the Stanford Medical Community for Peace and the Santa Clara Central Labor Council, begins at 9 a.m. Saturday in the Physics Lecture Hall, Room 100. It is open to the public and there is no registration fee.

Speakers at the morning session will be Harris Martin, assistant professor of Asian studies at San Jose State College, who will speak on "The War in Southeast Asia;" Douglas Korty, research economist at the Pacific Studies Center, on "The Impact of the War on the Economy;" and Einar Mohn, Western director of the Teamsters, whose topic is "The War and Organized Labor."

California Assemblyman John Burton, co-chairman of the State Legislature's joint committee on conversion to a peacetime economy, will also appear at the morning session.

At 11 a.m. Dwight Simpson, professor of political science at San Francisco State College, will moderate a panel discussion on "The University and the War." Panel members will be Alan S. Manne, professor of economics at Stanford; Norm Goodman, student in political science; and Art Carter, secretary-treasurer of the Contra Costa Central Labor Council.

In the afternoon, workshops will focus on the areas of health care services, political strategies and tactics, problems of conversion to a peacetime economy, and a labor/student coalition for a progressive society.

The workshops will be conducted by Dr. Halsted Holman, chairman of the Department of Medicine at Stanford; Sidney Roger, labor commentator for radio station KPFA; Richard Groul, executive secretary of the Alameda Central Labor Council; Leo Stodolsky, physicist at Stanford Linear Accelerator Center; Tim Coburn, graduate student; Les Chilton of Boilermakers, No. 6; William Ferguson, president of the Metal Trades Council; James P. McLoughlin, secretary of the Santa Clara Central Labor Council; and Gary Feldman, medical student.

Attention: Science Writers.

STANFORD -- The chemistry of the brain will be the topic of an all-day conference Friday, June 26 at Stanford University School of Medicine.

The symposium, "The Pharmacology and Physiology of Monoamines in the Central Nervous System," will begin at 9 a.m. in Room M104 of the Medical School. It is sponsored by the Department of Neurology at Stanford and Eaton Laboratories of Norwich, N.Y.

"Monoamines are a group of chemical substances which can act as transmitters of information between nerve cells in the brain," according to Dr. William W. Hofmann, a Stanford neurologist and co-chairman of the symposium. "It is only recently that we have begun to identify these individual substances and understand the specific roles they may play in both mental and neurological diseases."

Dr. Oleh Hornykiewicz of the Department of Pharmacology and the Clarke Institute of Psychiatry at the University of Toronto, is chairman of the conference and will be a featured speaker. In 1961 Dr. Hornykiewicz reported that persons suffering from Parkinson's disease had lower amounts of these monoamines, specifically dopamine, in their brains.

"This was the first definite correlation between the disease process and measured amounts of these compounds," Dr. Hofmann says. Subsequently, it was discovered that a new drug, L-Dopa, was broken down by the body into dopamine, thus increasing the deficient supply in the brain and relieving the symptoms of Parkinson's disease in many patients.

Another speaker at the conference will be Dr. Seymour Kety of the Department of Psychiatry at Harvard Medical School. He will discuss the role of monoamines in mental processes.

The meeting at Stanford is the third in a series of conferences sponsored by Eaton Laboratories to extend the knowledge of the role of monoamines, such as the dopamine-Parkinson's disease correlation, to other areas of brain function. Leading neurologist and neuropharmacologists from throughout the nation are expected to attend.

STANFORD--Eleven graduating medical students at Stanford University School of Medicine have been elected to Alpha Omega Alpha, the national honor medical society.

The new members are Howard D. Arkans, son of Mr. and Mrs. Leonard Arkans, 9120 SW 45th St., Miami, Florida; William H. Clewell, son of Mr. and Mrs. William H. Clewell, 17432 Paine St., Fontana, California; Nancy Lee Johnson Harris, daughter of Mr. and Mrs. Robert L. Johnson, 7 Esquire Ct., Novato, California; Douglas R. LaBrecque, son of Dr. and Mrs. Frederick C. LaBrecque, 132 Columbia Blvd., Waterbury, Connecticut; Keith I. Marton, son of Mr. and Mrs. Lawrence B. Marton, 703 West 3rd Place, Mesa, Arizona; Joe F. Neal, son of Mr. and Mrs. M. Hiram Neal, 1348 Clark Road, Modesto, California; William J. Raskoff, son of Mr. and Mrs. Max L. Raskoff, 6630 Drexel Ave., Los Angeles, California; and Douglas D. Richman, son of Dr. and Mrs. Daniel P. Richman, Darbrook Road, Westport, Connecticut.

Three of the graduating medical students were chosen for the honor society in their fourth year. They are Robert C. Aber, son of Mr. and Mrs. Donald C. Aber, 2 South 11th St., Easton, Pennsylvania; Michael P. Alexander, son of Mr. and Mrs. Joel Alexander, 420 South Blvd., Evanston, Illinois; and Bobbette K. Ranney, daughter of Mr. and Mrs. Robert C. Ranney, Jr., 434 N. Harrison Avenue, Kirkwood, Missouri.

STANFORD--Six years ago, Mrs. Ruth Bell of Placerville underwent what was then described as an "highly experimental" operation at Stanford University Medical Center. It was a kidney transplant, only the second in the Medical Center's history and significantly different from the first because the donor and recipient were not identical twins.

Today (Friday, June 19), Mrs. Bell, 28, and her mother, Mrs. Wilma Davis, who donated one of her kidneys to her daughter, were honored at a gathering at Stanford and presented with certificates of appreciation for their contributions to the field of organ transplantation.

"Mrs. Bell's operation was important in several aspects," according to Dr. Roy Cohn, professor of surgery and key developer of the kidney transplant program at Stanford. "It definitely proved to us that transplants between non-identical recipient and donor were technically feasible."

"It also provided us with vital information on the phenomena of tissue rejection," Dr. Cohn said. "Mrs. Bell's case was the cornerstone for clinical research and development of the now sophisticated means of detecting the rejection reaction and providing treatment to reverse and control it."

"I should also add that both Mrs. Bell and her mother were excellent and cooperative patients," Dr. Cohn noted. "Without the understanding and willingness of Mrs. Davis to be an organ donor, the transplant would not have been possible."

Just prior to Mrs. Bell's transplant in July, 1964, Stanford researchers reported at the American Medical Association convention that in animals they had found a reliable method to indicate when drugs should be administered to suppress the rejection mechanism. By administering radioactive tracer drugs, the investigators were able to obtain measurements of the transplanted kidney's blood supply. They found a fall in the blood flow to the kidney was the first detectable signal that rejection was taking place.

Mrs. Bell's transplant was the first time the method was used on a human patient. Physicians did detect and successfully treat Mrs. Bell's kidney for rejection and she still takes very small dossages of anti-rejection drugs. Her kidney function has remained stable for the past 4 1/2 years.

-more-

Dr. Samuel L. Kountz, who served as a surgery resident on the transplant team in 1964 and now heads the kidney transplant program at the University of California Medical Center, expressed his appreciation to Mrs. Bell and her mother and also said that Dr. Cohn should be commended for his pioneering work in organ transplantation.

"This case is particularly important because every indication is that certain transplants may be expected to survive indefinitely and will not require retransplantation after three to five years as we thought might be necessary," Dr. Kountz said. "This places kidney transplantation beyond the realm of research, making it a truly therapeutic procedure."

After her transplant operation, Mrs. Bell and her young daughter moved to Placerville in 1966 where she attended American River College for two years. She is presently attending Sacramento State College and has a 3.5 grade point average. She will receive a degree in education next year.

"It is impossible for me to express my gratitude," Mrs. Bell said Friday. "Before the transplant, I had been told my condition was hopeless. Now I've returned to a completely normal life."

"It is rewarding to know that those things which were learned from my operation have been applied in saving the lives of others," she said.

Since Mrs. Bell's operation, almost 100 other kidney transplants have been performed at Stanford University Medical Center.

STANFORD -- A distinguished surgeon and a noted biochemist have been named as the first occupants of two new endowed chairs at Stanford University School of Medicine.

They are Dr. Roy B. Cohn, Walter Clifford Chidester and Elsa Rooney Chidester Professor of Surgery, and Dr. Paul Berg, Jack, Lulu and Sam Willson Professor of Biochemistry.

"It is especially fitting that the honor associated with an endowed professorship be accorded Dr. Cohn and Dr. Berg," Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, said today. "Both have served the University with distinction and made significant contributions to their respective fields."

Dr. Cohn, a nationally recognized leader in the field of surgery, was the key figure in developing the kidney transplantation program at Stanford. He also innovated many surgical techniques including the original experimental method of closing defective holes in the heart. He joined the faculty in 1938 after serving as a resident at Massachusetts General Hospital for six years and from 1939-41, as a Tata Fellow in cancer research, was co-chief of surgery service at Tata Memorial Hospital in Bombay, India. From 1942-46, Dr. Cohn served with the U.S. Army in the European theater during World War 11. He returned to Stanford following his military service and was named a professor of surgery in 1959.

Dr. Berg, a distinguished biochemist, received the B.S. degree (1948) from Pennsylvania State University and the Ph.D. (1952) from Western Reserve University. From 1952-54 he was a postdoctoral research fellow and a Scholar in Cancer Research of the American Cancer Society at the Institute of Cytophysiology in Copenhagen and at Washington University School of Medicine in St. Louis. After serving on the Washington University faculty for four years, he came to Stanford in 1959. In 1963 he was named California Scientist of the Year by the California Museum of Science and Industry for work concerned with decoding the genetic messages which determine how living cells make proteins.

Dr. Berg was named chairman of the Department of Biochemistry at Stanford last month. His research interest is in the role of viruses in the induction of cancer.

-more-

Two new endowed chairs

222

Funds for the Chidester endowed professorship were donated by John Hartman Chidester, the only son of Dr. Walter Clifford Chidester and Elsa Rooney Chidester. Mr. Chidester died in 1968.

Dr. Chidester supervised the construction and activation of Mills Memorial Hospital in San Mateo and until the time of his death was Chief of Staff. Mrs. Chidester, who still resides in the family home in Hillsborough, graduated in 1906 from the Lane Hospital Training School for Nurses conducted by Cooper Medical College, later to become the Stanford University School of Medicine.

The Jack, Lulu and Sam Willson Professorship bears the name of a prominent California family. Alfred John Willson, who was known affectionately as "Jack," came to California from England as a young man. For more than 40 years he was associated with the Hercules Powder Company at Pinole, Calif. Mrs. Willson, the former Lulu Nicholl, was the daughter of John Nicholl, who came to California from New York in the 1850's and was one of the founders of the City of Richmond.

Their son, Sam G. Willson of Oakland, a retired contractor, donated the funds to Stanford.

STANFORD -- Three Palo Altans have been appointed to the Board of Directors of Stanford University Hospital, University President Kenneth S. Pitzer announced today.

They are Conrad F. Gullixson, Mrs. O. Meredith Wilson and Frank H. Roberts.

Another Palo Altan, Kirk Jeffrey, who has served on the Board since 1968, was named president of the Hospital governing body.

Gullixson and Roberts are attorneys, and Mrs. Wilson is the wife of the Director of the Center for Advanced Study in the Behavioral Sciences. Jeffrey is president of the Stanford Bank. Gullixson had previously been on the Board from 1962 to 1968, when he left to serve on the Palo Alto City Council.

Stanford University Board of Trustees appointed the new members to replace three long-time members the Board who are resigning. They are James E. O'Brien of Palo Alto, Mrs. Edward H. Heller of Atherton and John Stern of Palo Alto. The resigning members have been Directors since the early Sixties, when the Hospital was jointly owned by the University and the City of Palo Alto, and all were reappointed in 1968 when the City's portion was bought by the University.

Other officers on the Hospital Board are Dr. Alejandro Zaffaroni of Atherton, who is president of Alza Corporation, as vice-president; and John Santana Jr. of Palo Alto, who is vice-president of Peninsula Creamery, as secretary-treasurer.

Three others continue on the nine-member Board: Robert H. Klein of Portola Valley, John A. Minor of Menlo Park, and Raymond F. Rohrs of Palo Alto.

STANFORD--Stanford University School of Medicine presented awards to eight graduating students at the annual senior class convocation Sunday evening(JUNE 14).

Diplomas were presented to 60 men and 8 women medical graduates. The School also presented six master's degrees, to four men and two women; and 21 Ph.D's, to eighteen men and three women.

At the convocation, William R. Brody received the Dr. and Mrs. Joseph Fife Surgery Award, given annually to the outstanding student in surgery.

Joe Ford Neal received the Robert H. Alway Book Award. Named in honor of Dr. Alway, dean of the Medical School from 1958 to 1964, the Book Award is given to a student who has "availed himself especially well of the Stanford five-year plan."

David G. Deneau received the L.A. and Marian S. Hopkins Award in Dermatology.

The winner of the Lowell A. Rantz Memorial Award "to the student who has distinguished himself in the field of infectious diseases" was Douglas D. Richman.

The Harold K. Faber Pediatric Award was shared by Howard D. Arkans and Bobbette K. Ranney recognition of outstanding accomplishments in pediatrics and of potential as a contributor to child health. Miss Ranney also received the Janet M. Glasgow Award of Achievement from the American Medical Women's Association.

Douglas R. LaBrecque received the Borden Undergraduate Research Award in Medicine given by the Borden Company Foundation, Inc., to the senior student who has completed the "most meritorious" research during his medical training.

Dr. James B.D. Mark, professor of surgery and acting associate dean for student affairs, presented the awards.

Michael Paul Alexander received the Upjohn Achievement Award, given by the Upjohn Company to the senior exhibiting "outstanding clinical performance."

Patrick Michael Sullivan, representing the class, presented the annual Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine to Dr. Mark G. Perlroth, assistant professor of medicine, cardiology.

-more-

Four Henry J. Kaiser Awards for excellence in teaching were presented--recipients were Drs. Roy H. Maffly, associate professor of medicine; William B. Pratt, assistant professor of pharmacology; Allen B. Barbour, associate professor of clinical medicine and head of the division of ambulatory medicine; and Saul A. Rosenberg, associate professor of medicine and radiology.

The faculty address was delivered by Dr. Norman E. Shumway, professor of surgery and head of the division of cardiovascular surgery. Following his address, Dr. Robert J. Glaser, vice-president for medical affairs and dean of the School of Medicine, administered the Hippocractic Oath and presented the diplomas.

Award winners and their parents' names and addresses are listed below:

CALIFORNIA--	Daly City:	David G. Deneau, Mr. and Mrs. George E. Deneau, 125 Coronado
	Modesto:	Joe F. Neal, Mr. and Mrs. M. Hiram Neal, 1348 Clark Road
	Stockton:	William R. Brody, Dr. and Mrs. Yale Brody 726 Rose Street
CONNECTICUT--	Waterbury:	Douglas R. La Brecque, Dr. and Mrs. Frederick C. LaBrecque 132 Columbia Boulevard
	Westport:	Douglas D. Richman, Dr. and Mrs. Daniel P. Richman Darbrook Road
FLORIDA --	Miami:	Howard D. Arkans, Mr. and Mrs. Leonard Arkans 9120 S.W. 45th Street
ILLINOIS--	Evanston:	Michael P. Alexander, Mr. and Mrs. Joel Alexander 420 South Boulevard
MISSOURI--	Kirkwood:	Bobbette K. Ranney, Mr. and Mrs. Robert C. Ranney, Jr. 434 N. Harrison Avenue

STANFORD -- Dr. John L. Wilson has been named acting dean of the Stanford University School of Medicine.

The appointment of the 55-year-old surgeon, announced Monday by Stanford University President Kenneth Pitzer, will be effective September 1.

Dr. Wilson will succeed Dr. Robert J. Glaser, vice-president for medical affairs and dean of the medical school, who will leave Stanford at the end of the academic year to become vice-president of the Commonwealth Fund of New York.

The new acting dean joined the Stanford medical faculty in 1968 as a professor of surgery, an associate dean, and director of Area 111, Regional Medical Programs. In his latter capacity he planned the groundwork for cooperative medical programs related to heart disease, cancer and stroke under a grant of $586,000 from the National Institutes of Health.

Prior to coming to Stanford, Dr. Wilson had served as dean of the Faculties of Medical Sciences at the American University of Beirut, Lebanon.

Dr. Wilson was born in Sturgis, Kentucky, and received his M.D. degree from Harvard Medical School in 1939. He is a specialist in thoracic surgery. He has held academic appointments at Stanford medical school (1949-52), Washington University School of Medicine, St. Louis, Mo. (1952-53), and the University of California, San Francisco (1958-60).

In 1955 Dr. Wilson received the Order of Merit of the Republic of Lebanon.

On Mondays and Thursdays around noon two casually dressed white-haired men stride into the Stanford University Medical Center.

Barney Brandt and Col. Edward Joseph, U.S. Army (Ret.) of Palo Alto, are coming for a visit with patients.

When Brandt and Colonel Joseph retired several years ago (Brandt from a successful insurance agency business), they did not retire from productivity. They turned their energies to realms where energies are really needed.

One of those realms is the day patient services section of the Stanford University Medical Center Auxiliary. There are three men in the 1,000-member organization.

"I've been a very sick man at various times during my life," Barney says. "I'm not a churchgoer, but I'm grateful for my blessings. Too many people take and never give. If there is something I can do to help out here, I'm glad to do it."

A similar sentiment is voiced by Colonel Joseph, who joined the Auxiliary when his wife became a member four months ago. He admits he is not as experienced as Barney who has worked as a volunteer since 1963. "But I am becoming more useful as I get to know my way around the Medical Center. Obviously, I am here because I wanted to contribute something after my retirement," he says.

So the two men come to the Medical Center to see people, "bringing a breath of fresh air from the outside," and talk about things remote from hospitalization.

Pick up something from the gift shop for the fellow on the third floor. Do an errand at the post office. Relay word about a special need to the people who can fill it. Some afternoons they visit as many as 45 patients. A few remember their names; most just know that the two men volunteers have remembered them.

Then, they are off, bound for other activities. In the following week, Brandt and Colonel Joseph will be back, bringing a special warmth which would be very, very hard to replace.

Editors: photos available upon request.

STANFORD -- Who in a busy hospital can spare time to meet every patient, take him to his room, and then escort him out of the hospital when he is ready to leave?

Who will read books to someone recovering from an eye operation, or entertain half a dozen children in the pediatric ward?

Who can run errands for stationery or curlers--and even set a woman's hair?

Who? No one else but the volunteers.

The Stanford University Medical Center Auxiliary has more than 1,000 members, and each month more than 600 women (not to mention a few men as well) work in the Hospital. They contribute nearly 7,000 hours of work monthly in almost two dozen services. To match that amount of time, the Hospital would need 175 additional full-time employees.

There is no typical volunteer. The Auxiliary counts among its members teen-agers as well as women in their eighties. There are numerous mother-daughter combinations, and at one time there were two families in which grandmother, mother, and daughter were all volunteers. Membership of the Auxiliary even includes a group of airline stewardesses who spend their days off helping patients in the hospital.

"The common denominator all these people share is the desire to help others," says Mrs. Frances C. Boyd of Los Altos Hills, Auxiliary president. "They make that extra effort time and time again."

Perhaps the best measure of the impact of volunteers comes from the patients and their families. You only have to accompany a volunteer on her rounds to begin feeling this impact. Maybe you are a Pink Lady or her 16- to 17-year-old counterpart, a Candy Striper, who is delivering flowers to a patient's room. A woman who cannot sit up because of a cast girdling her midsection finds a willing pair of hands ready to feed her for lunch or dinner.

In another room, a man who has read all the magazines in the ward rejoices finding a book he wanted to read in the Pink Ladies' book cart. Another patient is chauffered on a wheel chair out from the floor to one of the patios of the Medical Center.

Next you go to the playroom. Several children sit next to a flannel board while an Auxiliary member tells fables and illustrates them with figures of the characters. The children's interest lights their faces.

And so you move throughout the Hospital--to an orthopedic ward, where a patient thanks a Pink Lady for bringing him a magazine. "I could have walked to the Gift Shop, but it would have worn me out." Or to the maternity ward where half a dozen mothers have flocked about the shopping cart.

-more-

Being a Hospital volunteer requires physical stamina. Mrs. John Winterburn of Menlo Park, used to wear a pedometer when she first began in Escort Service. On a typical four-hour tour of duty Mrs. Winterburn logged three and a half or four miles. Escort women transport many patients to appointments in departments such as X ray and physical therapy. They also take specimens from nursing stations to laboratories, pick up prescriptions at the Hospital Pharmacy, and take discharged patients to the main entrance when they are ready to leave the Hospital.

From a woman's point of view, one of the most satisfying places to help out at the Center is Pediatrics. The Pink Ladies' two domains are the playrooms in the Hospital and the outpatient clinic where many mothers leave their children during visits.

Volunteers are equally attentive to visitors. They act as guides for public tours, serve coffee in the emergency room, and help friends and relatives during patient visiting hours.

Not all of the work of the volunteers goes on where it is readily visible. Much of it, of necessity, must go on behind the scenes.

Some work is administrative. Scheduling, maintaining address lists, getting replacements--all this consumes time. New members are trained and given orientation in hospital procedures. Another area where training goes on, but with a different purpose in mind, is at the nursing stations. Candy Stripers who have a strong interest in health careers are given a chance to serve as volunteer nursing clerks. Thus they get a closer view of what it is like to work as a professional in a hospital.

Other volunteers contribute in a different way. Mrs. James J. Saitta of Palo Alto, for instance, makes Pinky Puppets. These are hand puppets dressed either in the Auxiliary's pinafore pink, or as white-capped nurses. Pink Ladies give these to children and other patients. They have distributed 10,292 puppets in the past 10 years.

Another behind-the-scenes effort goes on each morning before the Auxiliary's Gift Shop opens. The previous day's receipts must be tallied and so a small group of money counters assembles to get the job done. The Gift Shop, the major source of Auxiliary income, netted $38,000 last year.

The surplus is used for good works in two major areas: contributions for Hospital programs and equipment, and loans for patients, interns and residents.

The Auxiliary recently donated $25,000 to the Hospital to renovate space in its annex, the Hoover Pavilion, for reconstructive surgery. It has also pledged $50,000 more for the project for the next 3 years. Another $20,000 was donated to buy bedside monitoring units for the Coronary Care Unit.

A report just issued to commemorate the Tenth Anniversary of the Stanford Hospital Auxiliary shows that since 1960 the volunteer organization has contributed $205,792 in gifts to the Stanford University Hospital. In addition, volunteers have recorded 731,000 hours of service.

Dr. Thomas A. Gonda, hospital director, says volunteers represent "a tremendous community investment in the Medical Center. They provide the 'personal touch' to the delivery of health care at Stanford."

Much of what volunteers do goes unnoticed except by those involved. A patient is cheered, a lost visitor is guided on her way, and the world goes about its business. The thanks come in helping, and that is the way the volunteers like it.

###

Members of the community who wish more information about the opportunities for volunteer service at the Stanford University Medical Center may call 321-1200, Extension 5103, between 9:30 a.m. and 4 p.m. weekdays. Since many of the adult volunteers are on vacation during the summer months, the Auxiliary is especially interested in recruiting young people to serve as Candy Stripers.

WASHINGTON -- By continuing to reduce expenditures for medical research and education, the federal government is tampering with the health of future generations, a Stanford University medical scientist said Thursday, (JUNE 11).

Dr. Halsted R. Holman, professor and chairman of the department of medicine, said he finds the proposed federal budget in the area of health "very disturbing."

"Medical care of high calibre cannot be achieved without a firm foundation in medical teaching, in an efficient, comprehensive mechanism for the delivery of care and in medical research," he said.

Dr. Holman testified in his capacity as president of the American Society for Clinical Investigation before the House Appropriations subcommittee. The subcommitteee is holding hearings concerning the 1971 budget of the Department of Health, Education, and Welfare.

He said the proposed support of health programs for the coming year is substantially inadequate. Research expenditures are to be cut below the level for 1965 with no correction for inflation. He made these points:

. U.S. medical schools now graduate 9,000 medical students a year. To eradicate the deficit in physicians, the number of annual graduates must be increased to about 15,000. This requires enlarging classes and construction of new medical schools. However, funds for construction of teaching facilities will be further reduced below the 1970 level and no funds are included for construction of research facilities.

. Nearly 12,000 faculty members for medical schools and continuing education programs will be needed by 1975. Yet training programs for these medical teachers will be reduced because of lack of funds.

. Medical schools wish they could attract as many capable young people into medicine as possible. But medical education is costly and beyond the reach of many students. Most students come from upper income families. Only 2.8 per cent of medical students come from minority groups though minorities comprise more than 12 per cent of the population. Nonetheless, student loan and scholarship funds will be reduced to levels below those of 1970, which were already only one-third of the amount needed.

. Under the proposed federal health budget, medical schools will find it increasingly difficult to experiment with programs of delivery of medical care.

Dr. Holman said present amounts devoted to these programs comprise considerably less than one-half of 1 per cent of the gross national product, and are not more than 4 per cent of total health expenditures.

"The programs themselves are not the cause of inflation and curtailing their support will hardly cure inflation," he said. "It will exact a toll in the health of the nation in the years to come.

"Funds for programs of the National Institutes of Health and related agencies are a cornerstone of medical education. There is no alternative source of support," he said.

City Editors: Dr. Lederberg is scheduled to deliver his testimony at 10 a.m., Wednesday (June 10) in Room H164, Capitol Building, Washington, D.C.

ADVANCE FOR RELEASE WEDNESDAY, JUNE 10, 1970

WASHINGTON, D.C. -- A Stanford University Nobel Laureate Wednesday proposed formation of a national Genetics Task Force to coordinate genetics research, to identify areas of imminent clinical application, and to set priorities for federal support.

Dr. Joshua Lederberg, professor of genetics, said the task force would consist of an advisory group of experts in genetics or related research with the coordinating panel appointed by the National Institutes of Health from its various institutes and divisions.

Dr. Lederberg made the proposal in testimony before the House Appropriations subcommittee, chaired by Rep. Daniel J. Flood (D-Pennsylvania). He spoke on behalf of the National Cystic Fibrosis Research Foundation.

The noted geneticist told the subcommittee that 15 newborn babies out of every 100 each year can expect at some time in their lives to manifest an inherited disorder. But American medicine today is totally unaware that a genetic disease problem of such dimensions exists and has no coordinated program for dealing with it.

He detailed the functions of the Task Force as follows:

- It would serve as a clearing house for communications concerning research progress in genetics.
- It would identify areas of research of potentially high and imminent pay-off, and provide useful guidance in funding.
- It would work out a model of research strategy for progress in the new biochemical-genetic medicine.

Dr. Lederberg also urged that $10 million in additional funds be appropriated for fiscal 1971 to support genetic research projects. The allocation of funds, over and above the normal NIH budget, would make possible genetics-related research "without penalty to other important areas of health research," he said.

With antibiotics to cure bacterial infections and the promise soon of broad-spectrum drugs against viral infections, the geneticist said a larger and larger proportion of the country's health burden is invested in hereditary diseases.

And, noting that at least 25 per cent of all hospital beds and of all institutional places for the handicapped are occupied by persons suffering some degree of genetic disease, Dr. Lederberg observed:

"Some authorities expect the nation's health burden attributable to genetic diseases to double in the next five years."

He said an increasingly complicated environment--with a growing number of drugs, food additives and environmental pollutants--raises the possibility that some new environmental factors may cause mutations that would result in either new or more genetic diseases, or both.

-more-

Dr. Lederberg predicted that development of genetic therapy will probably have consequences far beyond the range of purely hereditary diseases because many other major health problems--cancer, heart disease, schizophrenia, and many forms of mental retardation--have underlying hereditary causes.

He said up to now there has been little hope for coming to grips with the genetic disease problem because of the immense complexity, lack of appropriate knowledge and medical technology.

But Dr. Lederberg added, "Developments in the fields of molecular biology and biochemical genetics within the past few years and months now, for the first time, give us reason to expect that we shall soon be able to treat and perhaps even cure many of these disorders."

It was four years ago, he said, that scientists deciphered the genetic code, the so-called "Dictionary of language of life," according to which chemical instructions are written in the molecular structure of the genetic material for determining the form and function of all living things.

"Now, however, I can tell you that, quite unexpectedly, scientists at the National Heart and Lung Institute of the National Institutes of Health are hoping soon to apply the knowledge of the code--and particularly, the chemistry that was developed in the course of deciphering it--for the first time to the treatment of human disease, a fatal blood disease of children, called beta thalassemia."

Additional progress, said Dr. Lederberg, has been made in the identification of the hereditary nature of nearly 2,000 human diseases. Understanding of the genetic basis of these diseases is enabling physicians to detect carriers, or probable carriers, of defective genes and to counsel prospective parents on their chances for having defective children.

His major point, Dr. Lederberg told the subcommittee, was that "the grandest predictions made for the fields of molecular biology and biochemical genetics have had a way of being battered by reality in less than the allotted time.

"I can see no reason why this remarkable record cannot be improved upon, even more for the benefit of humanity, if the moment were seized and given guidance by developing a strategy for progress in the new biochemical-genetic medicine."

He pointed out further that the advances made up to now in genetic medicine came about, not by any systematic plan of governmental support for this research, but as a result of the scientists' resourcefulness.

As proof of his assertion he cited that scientists "have been forced to 'bootleg' biochemical-genetic and molecular-biological research under the guise of projects on infectious, chronic, allergic or degenerative diseases, organ transplantation and the like."

Dr. Lederberg remarked: "It is important to realize that, without such bootlegging, we would probably not yet have deciphered the genetic code, if, indeed, we would know for sure, even now, that one existed."

Turning to the question of research fund cutbacks, Dr. Lederberg said they threaten not only to forestall development and delivery of new medical technologies to the sick, but reduce the number of competent men and women who will continue this vital work.

He argued that grant applications for genetics research are scattered diffusely among so many study groups at NIH that there is no direct way of finding out the actual backlog. The backlog, he explained, is made up of grants which have been evaluated by independent experts, deemed deserving of pursuit, and approved, but have not been funded. The NIH-wide backlog of approved but unfunded projects for all medical research has risen lately to approximately 30 to 40 per cent of all approved grants, he said.

"The inability of this system to give an accurate overview of all genetics-related research is significant," Dr. Lederberg said, "because work in this area lacks the continuity that is so necessary for developing a strategy for the most effective planning, funding, and coordination."

Editors: The following is sent in response to a number of local queries concerning Stanford's role in the work leading to the synthesis of a man-made gene by Wisconsin scientists.

STANFORD -- Technology developed by a Stanford University biochemist played a major role in making possible the synthesis of a man-made gene by University of Wisconsin scientists, Dr. Paul Berg, professor and chairman of the department of biochemistry, said Wednesday.

Asked for comment about the synthesis of a man-made gene by the Wisconsin team headed by Nobel Laureate H. Gobind Khorana, Dr. Berg called it "an extraordinary achievement in the field of genetic chemistry. Although a first step, I see the greatest reward from this accomplishment to human welfare in the cure of disease."

Dr. Berg said that man's scientific achievement is always built on the work of others who have pioneered independently in chemical work.

He mentioned specifically Dr. Robert I. Lehman, professor of biochemistry at the Stanford University School of Medicine, and Dr. Charles C. Richardson, now of Harvard University. In 1967 they discovered an enzyme called DNA ligase or "joining enzyme," which provided one of the tools in Professor Khorana's work.

Since a gene consists of some 100 nucleotides or chemical building blocks, it is difficult to synthesize it all at once. Dr. Khorana used the chemical trick of making shorter pieces of the gene of about 10 nucleotides each; then used the DNA ligase to "stitch" them into one segment.

The DNA ligase was also one of the tools used in 1967 by Stanford's Dr. Arthur Kornberg in synthesizing the biologically active genetic material of a simple virus.

STANFORD -- Stanford University scientists are applying man's most advanced tool, the computer, in heart replacement research.

Dr. Eugene Dong, Jr., assistant professor of cardiovascular surgery, is using a small, general purpose computer to design a prototype control system for an artificial heart and to look for techniques which will pinpoint the first evidence of rejection of a transplanted heart.

In the continued search for sure ways to detect the first hints of rejection, Dr. Dong and his research team are seeking greater efficiency in the care of heart transplant patients, as well as longer lives for them. Dr. Dong has been associated with Dr. Norman E. Shumway in heart replacement research since 1960.

"Many of our heart transplant patients have encountered acute or chronic rejection," says Dr. Dong. In acute rejection, the heart muscle itself is the target of the immunologic process. In chronic rejection, the arteries which serve the heart tissue are clogged and eventually choked off, cutting the heart's own supply of oxygen and nourishment.

"We hope to be able to manage both the recovery period and outpatient surveillance much more effectively," says the 37-year-old researcher. "Drug therapy will be more precise, thereby reducing the incidence of complications of therapy." The complications he is referring to are infections due to weakened immunity.

In the past two and a half years, 25 heart transplant operations have been done at Stanford. Eight of the patients presently survive.

Dr. Dong explains that two factors enabling the intensive search for early detection methods are the availability of data on human patients and the computer's capabilities to handle the data.

"Our primary laboratory tools in the assessment of whether heart muscle or vessels are being damaged are the electrocardiogram, ultrasound and the phonocardiogram," he says. "These give us, respectively, measurements of the electrical activity, the mechanical aspects (rate of motion, chamber size, and wall thickness), and heart sounds.

-more-

"The computer can deal with the huge amounts of data generated by these tools," he says. "Its powers to reduce, standardize and organize the data, calculate rapidly and reproduce experiments exactly are an immense help to us in this work."

Running parallel to the rejection research is the development of a method to control an artificial heart. Artificial hearts, Dr. Dong believes, will not supersede transplanted hearts. Instead, the procedures will go hand-in-hand. "Together they make up a complementary effort to achieve the common goal of treatment for patients with irreversible heart disease," he says.

Inserted in the body and powered by its own source, the artificial heart could maintain a steady lub dub pumping action, but by itself could not respond in exigent situations. For instance, alone it could not speed up when the body had an immediate increased need for blood.

The natural heart's rate is regulated by nerve signals from the brain and chemical changes in the blood. Transplanted human hearts have not reinnervated thus far in the history of transplantation, but are responsive to chemical changes in the blood. An artificial heart by itself would not be able to react to either nerve signals or chemical changes, and so would have to be allied with a mini-mini computer, also to be placed inside the body.

The Stanford scientists are in the very earliest design stage of the tiny control instrument.

"At present, the laboratory computer is helping us just to establish principles which will determine our guidelines," Dr. Dong says. "First we learned all we could about the responses of the natural heart to a specific group of stimuli. Now we are studying the responses of the transplanted heart to the same group of stimuli, because the transplanted heart, in common with the artificial heart, is not controlled by the central nervous system."

The initial control system, Dr. Dong predicts, will simulate the natural heart's regulatory mechanisms. "We will adapt those natural mechanisms we can to the requirements of the artificial heart," he says, "because the natural mechanisms are demonstrably efficient."

STANFORD -- The level of lead concentration in air may already be too high in the Bay Area and Los Angeles, a Stanford University pharmacologist warned at State Senate hearings in Sacramento Wednesday (July 29).

Dr. Sumner M. Kalman, professor of pharmacology at Stanford University School of Medicine, testified before the Senate Committee on Health and Welfare in support of a bill by Nicholas Petris (Dem. - 11th District), which calls for phasing out use of leaded gasoline in California.

Dr. Kalman said that estimates of the upper safe level of lead concentration in the air may be too high, and average levels measured in the two state metropolitan areas are approaching the upper limit, causing a hazardous situation.

"Most maximum allowable concentrations for toxic substances in air provide a large safety factor, usually 10-fold or more. If we are currently near the upper limit for a safe concentration of lead in air, we do not have an adequate safety factor," he testified.

When the human body is exposed to higher and higher levels of lead, controls increase the body's level of input and output. But at a certain level, the control mechanism is rendered ineffective by the body's finite capacity to excrete, the pharmacologist explained.

He stressed a wide range of differences in the population in individual responses to levels of exposure and other dangers. He cited subnormal kidney function, and metabolic variances, which can lead to harmful effects to the red blood cells of some individuals. Dr. Kalman estimates the number of people in the United States with inherited metabolic differences at one to two million. "Any insult with certain drugs or chemicals, including lead, would be expected to have adverse effects in red blood cells among these people," he said.

Scientists now have strong evidence that lead reduces the activity of an enzyme involved in the production of red blood cells, as well as damaging existing red cells, he reported.

Dr. Kalman said that he cannot arrive at any "threshold" level of lead exposure below which no metabolic effects are detectable. He noted the variances in the population, and the "extraordinary efficiency of absorption of lead through the respiratory system." In conclusion, he recommended using our power to control the intake of lead by removing it from gasoline.

Dr. Kalman testified on behalf of the Stanford Committee for Environmental Information, a group of medical scientists, ecologists, physicists and engineers, formed to provide analytical reviews of public issues concerning the impact of technology on environment.

EDITORS: Transmitted on Business Wire 7-23-70. Story released simultaneously by the National Cystic Fibrosis Research Foundation, New York.

WASHINGTON, D.C. -- The proposal by the National Cystic Fibrosis Research Foundation for establishment of a national task force in genetics has been adopted by the House of Representatives which Thursday (July 23) voted an appropriation bill providing $10 million for the study group.

The House acted in accordance with a recommendation made on behalf of the foundation last month by Dr. Joshua Lederberg, Nobel Laureate of Stanford University, in testimony before an appropriations subcommittee.

The House bill now requires confirmation by the Senate.

The task force would be composed of leading scientists in genetics research backed up by a coordinating panel representing the 10 national institutes of health and responsible to the overall director of the Institutes.

Dr. Lederberg urged formation of the task force as necessary to meet the growing challenge of the human genetic diseases, some 2,000 of which have come to be recognized in recent years. Relatively little is known regarding most of these maladies which are transmitted from parents to children by abnormalities in the hereditary material of cells, genes and chromosomes.

Cystic fibrosis is one of the most common of genetic diseases occurring once in approximately every 1,000 births. It causes irreversible lung damage and takes a high toll in lives among infants, children and young adults. One person in 20 is believed to carry the gene for cystic fibrosis.

Dr. Lederberg asserted that with the rapid pace of discovery in genetics laboratories, mankind stands on the threshhold of a new era in which hereditary disease, now incurable, may yield to "genetic medicine."

STANFORD -- The Supersonic Transport Program is one area where available facts, or lack of facts, should be carefully weighed before any decision for further funding is made, a group of Stanford scientists urged today.

In a letter to California senators Alan Cranston and George Murphy and members of the U.S. Senate Subcommittee on Transportation, Dr. John Farquhar, associate professor of medicine and chairman of the Stanford Committee for Environmental Information, urged that the subcommittee consider the following issues:

- The sonic boom represents a hazard to health and property
- There will be a serious airport noise problem
- Air pollution and depletion of the world's fossil fuel reserves will be increased
- The SST will be more dangerous than present commercial aircraft

"Present proposals are to restrict supersonic flight to ocean areas," Dr. Farquhar said. "However, since this will severely limit the marketability and economic success of the plane, it is reasonable to assume that pressure will be brought to bear to allow flight over land.

"Even if limited to the oceans, the booms would cause some problems with shipping, island population and perhaps oceanic life," he said. "On land the booms would cause widespread damage to structures and would very likely have important deleterious effects on human health."

He pointed out that because of these problems such countries as Britain, Canada, the Netherlands, West Germany, Norway, Sweden and Switzerland have banned or are considering banning supersonic overflights.

In regard to serious airport noise problems caused by the SST, Dr. Farquhar said the greatest concern is the anticipated greater lateral spread of noise on takeoff than is the case with present subsonic jets. "Communities in the vicinity of airports would therefore be exposed to increased amounts of noise despite growing scientific evidence for possible harm to human health that may result from noise levels of a lesser degree," he pointed out.

"The SST consumes enormous quantities of fuel, about 2.5 times as much per passenger mile as the jumbo jets at flight altitudes," Dr. Farquhar noted. "During takeoff about one ton of fuel will be consumed per minute. Switching to SST would therefore accelerate depletion of the world's fossil fuel reserves and increase air pollution."

"Air pollution in the vicinity of airports is an increasing problem and would be measurably worsened by the SST's outputs of nitrogen oxides, carbon monoxide, particular matter, unburned hydrocarbons and water vapor. The high fuel consumption at high altitude means that large amounts of water vapor and other combustion products will be exhausted into the very thin, cold upper atmosphere," Dr. Farquhar said.

-more-

"The meterological research done on this issue is clearly inadequate, particularly in the colder areas of the upper stratosphere," he stresses. "Many unknowns exist. For example, we believe that excessive cloud formation and changes in the earth's temperature could ensue if SST programs succeed in their anticipated frequency of flights."

In the letter to the subcommittee, Dr. Farquhar pointed out that the SST will be more dangerous in many respects than present commercial aircraft: 1) Loss of cabin pressure in lower altitude aircraft is serious but can be compensated for with oxygen masks; in the SST such loss of pressure would be catastrophic, 2) Inability to land at destination may be a major problem because the high fuel consumption permits only a very limited holding time, 3) SST landing and takeoff speeds are high and this subjects other aircraft to the hazards of wake turbulence and to differences in aircraft speeds within airport control zones, 4) Radiation exposure per aircraft mile would be greater than in present jets and the potential hazard of this needs further assessment.

An operational SST would be an extraordinary technological development requiring innovations greater than ever taken before in commercial aircraft," Dr. Farquhar said. "Comparable innovations in military aircraft are often accompanied by enormous cost overruns, failure to meet specifications and high accident rates in initial stages."

"Our committee was set up to disseminate information on environmental problems in the belief that public officials and the public will take appropriate actions on such matters when they know the facts," Dr. Farquhar said. "We feel that the SST program is one area where the available facts, or lack of facts, should be carefully weighed before any decision for further funding is made.

"We hope you will find out view of help in your decision as we believe the SST an important example of priority setting in allocation of our national resources," he concluded.

The Stanford Committee for Environmental Information is a group of medical scientists, ecologists, physicists and engineers. It was formed to provide analytical reviews of public issues concerning the impact of technology on our environment.

Vice chairman of the Committee is H. Russell Hulett, Ph.D., research associate, department of genetics.

STANFORD -- Stanford University School of Medicine has received a $243,000 grant from the National Institutes of Health for clinical research in heart transplantation.

The grant is the largest award of its kind in the area of heart transplant research, according to NIH officials.

"While clinical research in this field has been conducted at Stanford during the past two years, it was sustained on a limited basis from a few sources," according to Dr. Eugene Dong, Jr., assistant professor of surgery and principle investigator for the new research grant. "This federal funding which is scheduled to be renewed for two additional years will enable us to implement a longer-term, comprehensive study.

"The primary goal of our program will be a multi-discipline assessment of the therapeutic value of heart transplantation for humans," says Dr. Dong. "It will be conducted with the cooperation of a limited group of patients with advanced, irreparable heart disease."

Specific areas to be studied include:

- those types of cardiac patients who might benefit from transplantation;
- the role of tissue matching and its significance in long-term survival;
- early and late detection of cardiac rejection;
- immunosuppressive therapy and its complications;
- the characterization, management and prevention of infectious complications.

"Rejection remains a critical problem in heart transplantation," the surgeon says. "Patient survival is dependent on the early detection and treatment of this phenomena. — non !!

"Our experience to date has provided us with increasingly sophisticated means of detecting rejection episodes," he says. "We also have evidence indicating that those episodes treated earlier are reversed more easily during shorter periods of therapy and require smaller total amounts of drugs.

"Additional clinical experience is needed to confirm these important points," Dr. Dong says.

"Another goal of our program is to study important biological and physiological problems in heart transplantation," the surgeon notes. "We need increased understanding of how the human cardiovascular system is controlled and of the functional capacity of the transplanted heart.

-more-

"Sociological aspects of this procedure will also be studied," according to Dr. Dong. "Heart transplantation at Stanford has reached the stage where survival of the patient is not the only consideration. We plan to document that this procedure can return a person crippled by heart disease to a normal and productive life.

"This extensive project will also provide experience, both in research and patient care, to a diverse group of physicians in training at Stanford," Dr. Dong notes.

Co-investigator with Dr. Dong in the research will be Dr. Norman E. Shumway, professor and head of the division of cardiovascular surgery at Stanford and a pioneer in the field of heart transplantation.

In 1959, Dr. Shumway and a colleague, Dr. Richard Lower, now at the Medical College of Virginia, announced perfection of the surgical technique developed in animal research which is the basic technique used in human heart transplantation today. The succeeding nine years were spent by Dr. Dong and Dr. Shumway studying the immunologic problem of rejection and how to recognize and treat it.

The first human heart transplant at Stanford was performed in January, 1968. Since that time a total of 25 persons have received new hearts at Stanford. Eight of the patients survive today, seven of whom have been discharged from the hospital to resume normal lives. Four of the ten received their new hearts over a year ago with the longest survivor having lived 21 months to date.

"Stanford, by history, is committed to the study of this procedure and all its ramifications," Dr. Dong says. "Our experience thus far indicates that heart transplantation does have therapeutic value for certain patients, but that there are many unsolved and unexplored problems."

STANFORD -- Stanford University School of Medicine has received a $243,000 grant from the National Institutes of Health for clinical research in heart transplantation.

The grant is the largest award of its kind in the area of heart transplant research, according to NIH officials.

"While clinical research in this field has been conducted at Stanford during the past two years, it was sustained on a limited basis from a few sources,"according to Dr. Eugene Dong, Jr., assistant professor of surgery and principle investigator for the new research grant. "This federal funding which is scheduled to be renewed for two additional years will enable us to implement a longer-term, comprehensive study.

"The primary goal of our program will be a multi-discipline assessment of the therapeutic value of heart transplantation for humans," says Dr. Dong. "It will be conducted with the cooperation of a limited group of patients with advanced, irreparable heart disease."

Specific areas to be studied include:

- those types of cardiac patients who might benefit from transplantation;
- the role of tissue matching and its significance in long-term survival;
- early and late detection of cardiac rejection;
- immunosuppressive therapy and its complications;
- the characterization, management and prevention of infectious complications.

"Rejection remains a critical problem in heart transplantation," the surgeon says. "Patient survival is dependent on the early detection and treatment of this phenomena.

"Our experience to date has provided us with increasingly sophisticated means of detecting rejection episodes," he says. "We also have evidence indicating that those episodes treated earlier are reversed more easily during shorter periods of therapy and require smaller total amounts of drugs.

"Additional clinical experience is needed to confirm these important points," Dr. Dong says.

"Another goal of our program is to study important biological and physiological problems in heart transplantation," the surgeon notes. "We need increased understanding of how the human cardiovascular system is controlled and of the functional capacity of the transplanted heart.

Heart Transplant Deaths #23 and 24

FILE COPY

FOR FURTHER INFORMATION CONTACT: Jane Duff 415: 321-5310

Two heart transplant patients died over the weekend at Stanford University Hospital.

They were Francis J. McMahon, 50, 1 Lilac Drive, Atherton, and Irwin Donald Louderback, 49, 2686 - 22nd Avenue, San Francisco.

Mr. McMahon, who received a new heart May 21, died at 7 p.m. Saturday. He is survived by his wife, Rita and two children, Judy, 20, and Francis Jr., 22.

Mr. Louderback, who received his new heart May 19, died at 2:25 a.m. Sunday. He is survived by his wife, Crystal.

Causes of death in both patients are undetermined pending an autopsy.

STANFORD -- A retired major in the U.S. Air Force is reported in satisfactory condition today following a heart transplant operation Saturday night at Stanford University Hospital.

The recipient is Carlyle Townswick, 48. He received his new heart from an anonymous donor in a 4-1/2 hour operation performed by a team of surgeons headed by Dr. Norman E. Shumway.

Townswick and his wife, Margaret, live at 361 North West Street in Vacaville. They have two children, Carlynn, 15, and Robert, 22. Townswick, who retired from the Air Force in 1960, has suffered from heart disease for the past 8 years. He worked at the California Medical Facility in Vacaville until ill health forced him to quit in 1965.

In addition to Townswick, Stanford has nine other surviving heart transplant patients, seven of whom have been discharged from the hospital to resume normal lives.

Townswick is the 25th heart transplant patient at Stanford.

STANFORD -- Dr. Avram Goldstein of Stanford University School of Medicine will appear in an interview on NBC television's show "First Tuesday" tomorrow night (July 7) at 9 p.m.

The show reports on the use of the drug methadone to treat heroin addiction, and Dr. Goldstein, professor and chairman of the Department of Pharmacology, describes a methadone treatment program currently being conducted in Santa Clara County.

STANFORD -- The Scottish Rite Institute for Childhood Aphasia, an internationally known center for training and treatment of children with speech disorders, has been moved to a new home.

The Institute has been relocated to a recently reconstructed building on the grounds of the Children's Hospital at Stanford (formerly known as Stanford Children's Convalescent Hospital).

The move will give the Institute the needed space to expand its training, treatment, and research programs, according to Dr. Jon Eisenson, the Institute's director.

A part of the Stanford University School of Medicine, the Institute has been in operation for nearly nine years. For the past three years it was located in rented space at 1691 El Camino Real, Palo Alto.

The new building constitutes two interconnected prefabricated modules of about 4,000 square feet. They house the Institute's offices, observation rooms, and special equipment used to train aphasic children to perceive and comprehend speech and to learn to speak.

Aphasia is a disorder which impairs a child's ability in language functioning. This includes spoken as well as written language. There are thousands of children in the U.S. with aphasic language disorders.

The Institute serves as a referral center for patients from the San Francisco Bay Area, other states, as well as from foreign countries. As a unit of the Hearing and Speech Sciences Section of Stanford's Otolaryngology Division, the Institute treats severe cases of aphasia, does research to develop new techniques, and trains personnel to understand and work with the many manifestations and problems presented by aphasic children. Another of its functions is to counsel parents since family emotional problems are often bound up with the basic illness.

Treatment consists initially of teaching aphasic youngsters to appreciate the nature of symbols, particularly the symbols of the language code. This may be done by training children to match objects or pictures with written words, and to make them alert and eager to respond to instruction. Once some means of communication has been established with a child, clinicians launch into the long and arduous job of teaching him to discriminate between speech sounds and combinations of sounds, and eventually to speak and understand his native language.

Dr. Eisenson, who is also professor in hearing and speech science, directs the program, augmented by a staff including a pediatric neurologist, a psychologist and speech and hearing specialists. The research staff includes a linguist and a psycholinguist. The work of the Institute is supported by grants from the California Scottish Rite Foundation, and the National Institute of Neurological Diseases and Stroke.

Dr. Eisenson said the Institute was relocated "because our clinical and research work and the developing interests of the Children's Hospital are interrelated." He said he looks forward to increased cooperation between the Medical School, the Children's Hospital, and the Children's Health Council, Inc. Both of the latter are independent institutions associated with the Medical School and located on Stanford land near the Stanford University Medical Center.

-more-

In describing the research at the Institute, Dr. Eisenson said that all evidence needed to explain the severe delay of speech in aphasic children is unfortunately not yet available.

"What evidence we do have strongly suggests that aphasic children are lacking in the basic capacities to receive and decode speech--therefore they cannot make the necessary integrations for normal speech development," he said.

Dr. Eisenson cited children treated at the Institute at age five, who were found to have speech processing capacities of two-year-olds.

But the same children could respond to nonspeech sounds--music, noise, and animal sounds--in a normal way.

This observation, in Dr. Eisenson's opinion, supports a speculation that the left and the right hemispheres of the human brain are functionally different in regard to the kinds of sounds each processes.

"Scientists have known for a long time that the left part of the human brain is for talking and for listening," Dr. Eisenson explained. "But recent findings reported by the Haskins Laboratory in New York have shown that perception of nonspeech sounds such as musical tones and tonal patterns may depend more on the right hemisphere than it does on the left part of the brain."

This new evidence is particularly relevant for aphasic children whose perception of things appears to exclude speech, he said.

Noting that, although it is often diagnosed as mental retardation or deafness, aphasia usually implies no intellectual impairment. Dr. Eisenson said that if they are diagnosed sufficiently early, and the proper procedures and training initiated, aphasic children can often enter public schools as normal children at age six. Of the aphasic youngsters seen at the Institute, only one-third of them have confirmed brain damage. Almost all of them, however, do have perceptual disturbances for speech.

"Another thing we have found," he said, "is that emotional reactions of aphasic children seem to result from their aphasia--their inability to communicate--rather than being the cause of it, as was thought."

"Perhaps aphasic children are not prewired as well as they should be to integrate what they need, to be proficient receivers and senders of sound signals," Dr. Eisenson said. "They may be slower in their central nervous system maturation than our normal speakers or our even mentally subnormal speakers. They may develop perceptual defenses because of demands made on their system which are beyond their capabilities at the time they are made."

The Institute's new headquarters was designed by the resident architect's office of the Medical School, and Design Facilities Corporation of Newark, California. Total cost of the project was approximately $80,000.

EDITORS: Story transmitted on Business Wire 8/26/70. Dr. Nair will not be available at Stanford for interviews. He had to leave for Chicago where he can be reached. Phone 321: 791-3913. His report was prepared for delivery at the meeting of the Am. Soc. for Pharmacology and Experimental Therapeutics at Stanford.

(ADVANCE) FOR PM RELEASE THURSDAY, AUGUST 27, 1970.

STANFORD -- LSD fed to pregnant rats has caused biochemical defects in their offspring, a Chicago Medical School pharmacologist reported Thursday (Aug. 27).

The scientist, Dr. Velayudhan Nair, said that he observed no gross malformations or chromosomal damage in the offspring of rats exposed to LSD during pregnancy as has been reported by other investigators.

"However, most important and sinister are the subtle impairments in the development of biochemical systems in brain and liver noted in these animals," Dr. Nair continued.

The most significant damage appeared to be the suppression of the essential brain chemical, serotonin, he said. Another effect was LSD's apparent inhibitory effect on the development of liver enzymes which are responsible for neutralizing poisons before they take effect.

LSD's effect on serotonin in the brains of baby rats appears to be a significant finding, Dr. Nair said, because of the chemical's association with behavior disorders. These include sleep abnormalities and hypersexuality.

(NOTE: Several studies by neurophysiologists in recent years, including Stanford's Dr. William Dement, have shown that depletion of serotonin in animals has led to bizarre behavior.)

In another study, Dr. Nair fed chlorpromazine, an antipsychotic drug, to pregnant rats. Although this drug is chemically different and is known to block LSD's effectiveness when given in combined doses, it produced similar biochemical defects in the brain and liver of rat offspring.

Dr. Nair cautioned that one could draw no conclusions from the animal studies that could be applicable to humans.

"Functional implications of these findings related to such factors as behavior, drug action, and toxicity remain to be studied," he commented.

Dr. Nair presented his findings at the fall meeting of the American Society for Pharmacology and Experimental Therapeutics at Stanford University. He is director of therapeutic research at Michael Reese Hospital and Psychiatric Institute and professor of pharmacology at the Chicago Medical School. Co-authors of the report are Drs. David Bau, and Steven Siegel. Their work was supported by the State of Illinois Department of Mental Health.

The Chicago research team, according to Dr. Nair, has begun a study of the effects of LSD and other drugs on the biochemical and functional development of offspring in a variety of animal species.

"Much of the previous work in this area has been concerned with obvious birth defects," Dr. Nair said. "Unlike the gross abnormalities and malformations, biochemical changes are not readily evident and may be revealed only by specific tests. Biochemical or molecular defects may remain dormant and manifest themselves later in life as a functional impairment, a behavioral disorder, or abnormal reaction to drugs."

STANFORD -- Aspirin, used in conjunction with another anti-inflammatory drug in the treatment of arthritis, could reduce the effectiveness of that drug, two pharmacologists reported here Tuesday.

The scientists said they induced arthritis in rats, and then treated it with Indicin, a drug commonly used in arthritis treatment.

Next, the researchers treated the arthritic rats with Indicin combined with aspirin.

Even though the aspirin dosage was less than the amount needed to have a therapeutic value, it blocked the effect of the anti-inflammatory drug, the researchers said.

The report was presented by Drs. C. G. Van Arman and George W. Nuss of the Merck Institute for Therapeutic Research, West Point, Va. They spoke at the meeting of the American Society for Pharmacology and Experimental Therapeutics at Stanford University.

The researchers pointed out the phenomenon observed in the rats may not be true in man. "These findings are merely a warning," they said.

"But the implications of the entire study is that one should be extremely wary in clinical practice to suspect unfavorable interactions among drugs. One should take nothing for granted," Dr. Van Arman added.

He noted that in addition to aspirin, other drugs which are useful when used alone, have been known to interact in a similar fashion.

STANFORD -- Pharmacologists who want to do something about drug abuse must begin by teaching pharmacology to college undergraduates.

This is the opinion of Dr. Lloyd J. Roth, chairman of the Department of Pharmacology of the University of Chicago.

"We have been buried in our labs too long, doing research and teaching medical students," Dr. Roth commented.

"But college students are as much entitled to know about pharmacology principles as they are about learning chemistry and Russian."

The Chicago scientist said pharmacologists have been "derelict" in not teaching pharmacology as part of the undergraduate curriculum. Pharmacology, one of the basic biomedical sciences, is concerned with the effects of chemicals in the living organisms.

"You have to teach the fundamental principles of pharmacology before you talk to students about drug addiction," Dr. Roth said.

In addition to college undergraduates, Dr. Roth included high school teachers among those who should take pharmacology. He said he did not expect his idea to solve immediately the present drug crisis in the U.S., but it should be a part of any long-range solution to the problems.

Dr. Roth was in the audience when he made his remarks (Sunday night Aug. 23) at the opening of the fall meeting of the American Society for Pharmacology and Experimental Therapeutics (ASPET) at Stanford University. The session, sponsored by ASPET's public affairs committee, examined the role of the pharmacologist in drug abuse education.

Committee chairman Dr. Keith Killam of the University of California at Davis, noted the vast increase of the use of drugs in recent years has made the pharmacologist's role of central importance to society.

But the pharmacologist today has little or nothing to say about drug education, he argued. The drug education role is mainly played by television, public relations men, and Madison Avenue. These make no secret of their intention "to teach us how to live and seek a better life through chemistry."

School children get their education from street people, police departments, and former drug addicts.

"This is propaganda, not education," Dr. Killam said. "Pharmacologists have to be concerned with public education whether it has to do with cortisone, diuretics, or pot."

Another pharmacologist, Dr. Lowell M. Greenbaum of Columbia University, said his profession is woefully unprepared to deal with the drug abuse problem. We do not know why young people take drugs, and we are unprepared to deal with the reactions of the community, he said.

Dr. Killam said ASPET's public affairs committee plans to contact leading pharmacologists throughout the U.S. to continue discussions about the direction the Society should take in the area of public education.

One participant suggested the Society also look into the problem of physicians who prescribe drugs. "Over 50 per cent of them have had very little or no pharmacological training," he noted.

CITY EDITORS AND SCIENCE WRITERS

More than 1,500 pharmacologists are expected to attend the Fall meeting of the American Society for Pharmacology and Experimental Therapeutics at Stanford University August 23 through 27. Nearly 600 scientific papers, ranging from studies of alcohol to toxins, will be presented at the meeting, sponsored by the Department of Pharmacology of the Stanford University School of Medicine.

"Pharmacologists and Drug Abuse Education," is the first topic on the agenda. The meeting will be Sunday, August 23 at 8 p.m. in Tresidder Memorial Union, Room 270, followed by a teaching institute on "Pharmacology in the Changing Medical Curriculum," Monday, August 24 at 9 a.m. at Dinkelspiel Auditorium.

"Experimental Approaches to the Treatment of Alcoholism," will be discussed at a special workshop Tuesday, August 25 at 1:30 p.m. in the McCullough Building, Room 127; and a session titled, "Marijuana," will examine various pharmacological actions of the drug in humans and animals. The meeting will be Wednesday, August 26 at 9 a.m. in the Physical Sciences Building, Room 370.

In addition to these sessions, there will be two symposia of general interest in Dinkelspiel Auditorium: "The Pharmacology of Sleep," Thursday, August 27 at 9 a.m.; and "Developmental Pharmacology," Wednesday, August 26 at 9 a.m. The latter includes papers dealing with the general area of the effects of drugs on developing organisms.

The Press Office for the meeting will be located in Tresidder Memorial Union, Room 205 (ASSU Office). Programs and abstracts of all the scientific papers will be available at the Press Office.

STANFORD--"It was going to be a big summer for us," says April Saas, "our first baby and our first house."

But the summer had barely begun when April and her architect husband Fred Saas of Menlo Park, were hit head-on by a speeding car, in an auto crash June 6 on Foothill Road. When they came to, they were in Stanford University Hospital with numerous broken bones and some misgivings about the welfare of their unborn child.

Suddenly for the young couple, the summer panorama had dwindled to the confines of a long season in the hospital. The clouds didn't break until the birth July 23 of a healthy baby, Shawnee Elizabeth.

"We are sorry she had to find us in such adverse conditions," April says. The new mother seemed to be commenting about the girl she and her husband had been hoping and waiting for, as well as the actual baby girl who arrived. April hadn't even had a chance to select the baby's layette. But the couple had completed a Palo Alto High School evening course on childbirth and child care.

Fred Saas insisted on being present for the delivery, and because the traction apparatus associated with his bed is too extensive to permit wheeling him into the delivery room, a labor room at the hospital was specially equipped for the procedure. The unique arrangements which were made have occasioned some kidding for Fred from his Stanford physicians. One told Fred that he had helped the hospital to set a new standard of humane treatment.

The husband is welcome during delivery in many cases, but it was most ususual for the husband to be a patient.

Now April and Fred are sharing a room on the maternity floor of Stanford University Hospital. Looking out across the treetops they can see the cupola of the old Stanford Barn. Inside, the room is filled with flowers, baby presents, nurses and a steady stream of callers.

-more-

April's parents are on a prolonged visit to the West Coast from Pittsburgh, Fred is starting to see his architectural clients again, and Shawnee puts in intermittent appearances for love and nourishment.

Sometimes the crush of visitors in the hospital room seems almost too much, but April is in sympathy with Fred's lively interest in his business.

She spoke about the house they had just begun construction on for themselves: "When my husband asked me what I wanted, I told him simply that it had to be romantic," she says, "with window seats, stairways, fireplaces and views."

Fred designed it along the New England barn idea, with brick for the first story, wood on top. Mainly, it's going to be a house that's fun for people, he says.

He is a graduate of Cooper Union School of architecture in New York City, worked on the Stanford University staff for two years before going into business for himself in Palo Alto in 1968. While at Stanford, he was involved in design projects for the University Press, Stanford Coffeehouse, and the Placement Service.

His wife attended Smith College and graduated from Sarah Lawrence, where she majored in choreography. They met after both had come to live in San Francisco.

Both are vivacious, and their love of activity makes the long confinement difficult. But their friends and many people they didn't even know have helped to make it more comfortable. They are deeply touched by the kindness people have shown them. "It makes us very humble," they say.

Shawnee's antics amuse them, and life is taking on some aspects of normality again, although it will be several weeks to months until dismissal from the hospital. April says most of all she wants to get out into the sun.

(ADVANCE) FOR PM RELEASE MONDAY, AUGUST 3, 1970

ATLANTA, GEORGIA -- Infections, which have caused formidable problems in all organ transplant patients in the past, can now be successfully treated and controlled, a Stanford University specialist in infectious diseases said Monday.

Successful treatment of postoperative infections has significantly contributed to the survival of heart transplant patients at Stanford University Medical Center, said Dr. Jack S. Remington.

Speaking at the International Conference on Hospital Infections at the National Communicable Disease Center in Atlanta, he reviewed the past experience of various medical teams in kidney, liver, and lung transplantation, and reported what has been learned recently about heart transplant infections.

Twenty-five heart transplant operations have been performed at the Stanford University Medical Center since 1968. Eight patients are alive and live near-normal lives. Dr. Remington and his colleagues studied the first 20 patients and reported these findings:

- Of the 20 patients, 12 died. In five of them infection was considered to have directly contributed to death. There has been a 35 per cent survival of one year for the patients studied--the longest survival being 20 months.
- Six of the patients who lived beyond six months suffered a total of 16 separate infections from bacterial, viral, protozoal, and fungal organisms. Their infections were treated successfully with antibiotics.
- A total of 63 per cent of the infections in the heart transplant patients involved the lungs.

Dr. Remington emphasized that "successful diagnosis and treatment of infection contributed significantly to the survival rate of 35 per cent in our first heart transplant cases."

He attributed the success to careful studies which made possible the recognizing of infection early, and to the use of new methods to detect the specific infectious organisms in the patients.

They have proven life-saving in a number of instances, he said.

Dr. Remington is an associate professor of medicine at the Stanford University School of Medicine, and chief of Allergy and Infectious Diseases at the Palo Alto Medical Research Foundation. His associates are Drs. Edward Stinson, Charles Bieber, and Norman E. Shumway. Their study, the first of its kind on heart transplant infections, was supported by the National Institutes of Health, and the John A. Hartford Foundation, Inc. of New York.

-more-

"Infection among heart transplant patients is common," Dr. Remington explained. "It seems to stem mainly from the powerful drugs which must be given to prevent rejection of the new heart."

These drugs are known to suppress the body's ability to fight disease organisms. Dr. Remington noted that infection in all but one of the patients occurred four or more weeks after the heart transplant operation, and after each of the patients had been given a high dose of anti-rejection drugs.

Although infections may be related to other causes, drugs seem to be the critical factor in predisposing these patients to infection, Dr. Remington said.

Identifying infectious organisms early is important, according to Dr. Remington, because there is effective therapy for most of them. Prevention and treatment of all infections is not now possible because adequate drugs against certain organisms have yet to be found.

He suggested that better methods of cross-matching donor and recipient tissue might be one way to reduce the incidence of infection. Transplants between patients of similar genetic makeup require less drastic treatment with anti-rejection drugs. Such an approach would give heart transplant patients added protection against infections because their immunological system would be partially intact to fight disease organisms.

Dr. Remington urged that it is important to keep communication lines open among various transplant teams. He emphasized the need for continued support for investigations directed toward determining more effective means of diagnosis, treatment, and prevention of infections in not only heart transplant patients, but cancer patients and others who are treated with steroid and other anti-rejection drugs.

"Such diseases of 'medical progress' could be prevented or at least controlled," he said.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

STANFORD -- Stanford University medical researchers have introduced a new weapon in the battle against disease -- a computer to keep tab on dangerous bacteria and help to select which antibiotic drugs should be used to treat infections.

This new computer application includes a program of quality control, developed by scientists at the Stanford University Medical Center, to improve antibiotic sensitivity testing of organisms isolated from patients. These include the germs of staphylococcus, the pseudomonas, intestinal bacteria and others.

Knowing which of the different antibiotics are active or inactive against various micro-organisms helps doctors prescribe the right treatment for patients.

Unfortunately, standard tests for antibiotic sensitivity have not been completely accurate because present laboratory techniques can be influenced by many variables including human error, according to the researchers.

"Computer quality control improves the reliability of such tests," they emphasized, "and results in improved diagnosis, timelier treatment, and far less medical paper work."

The computer monitors results with all the commonly encountered bacteria in the hospital and reports changes in their resistance to specific antibiotics. By giving doctors this information periodicall appropriate treatment can begin as soon as the organism is identified.

The new adaptation of the computer is described in the current issue of the New England Journal of Medicine. Authors of the report are Dr. John Petralli, research associate; Edward Russell, Jr., a fourth-year medical student; Miss Adrienne Kataoka, medical technologist; and Dr. Thomas C. Merigan, Jr., associate professor and head of the Division of Infectious Diseases at the School of Medicine. Their work was supported by a grant from the National Institutes of Health.

The program utilizes a teletypewriter station in the infectious disease laboratory, connected to the Medical Center's Advanced Computer for Medical Research, an IBM 360/50 located at a distant site.

As laboratory findings are fed to the computer, it compares them with the data in its memory, immediately detects and challenges unusual results, and directs the technician to repeat the study of the organism in question.

When the work is done, the computer prints the organism's "antibiotic profile" for distribution to the physician.

In the past 10 months that the quality control program has been in operation, it has corrected 16 errors in each 100 organisms screened before results were issued to physicians, Dr. Petralli reported.

These have included 43 errors in identification of micro-organisms, and 551 changes in sensitivity categories.

-more-

Computer quality control for antibiotic sensitivity testing
222

To check dangerous bacteria isolated from hospital patients, laboratory technicians perform a standard test of growing bacteria cultures in small dishes, and exposing them to 12 antibiotics in each dish.

A day later, after the drugs have begun to work, the cloudy appearance caused by bacterial growth in the dish is replaced by a clear ring around each of the antibiotics tested. The rings, which differ in size, represent each drug's "inhibition zone."

Sensitivity of an organism to the antibiotics is determined by measuring the diameter of these "zones" and comparing them to a standard reference stored in the computer's memory bank. The computer then performs a quality control check by comparing the zone measurements with similar information obtained for each organism and antibiotic in the previous six months.

"It is in this respect that quality control has been most helpful," Dr. Petralli explained. "The computer has completely eliminated errors in conversion from zone size to sensitivity, which otherwise occur once in every 12 reports."

He noted that test results challenged by the computer had a 64 per cent probability of correction after restudy.

"The majority of these errors might have been clinically important, contingent on the specific situation," he said.

Differences in the quality of results emanating from clinical microbiology laboratories have been a cause of concern among physicians in the past, Dr. Petralli commented. Similar concern has led to a recent decision by the Food and Drug Administration to regulate drugs used in antibiotic sensitivity testing.

To give the computer its critical judgment, its programmers labored for two years. They studied, analyzed, and stored in its memory bank, data on more than 19,000 organisms isolated from patients at the Stanford University Hospital. From this, they instructed the computer to recognize and challenge antibiotic sensitivity results on 25 of the most commonly encountered bacteria.

The system is flexible, and information can be retrieved easily. Terminal rental, computer time, and data storage approximate the salary of one microbiology technologist. Each quality control check requires less than 10 seconds and it costs 5 cents per organism.

Other hospital laboratories in the area that cannot afford their own computers can also use the quality control system, Dr. Petralli said. A terminal connected by telephone lines to the Stanford computer can easily be installed to utilize the accuracy and speed of the program.

In addition to improving the accuracy of laboratory results for the benefit of patients, the computer has proved valuable in checking the work of laboratory technicians and students undergoing training.

Further use of the computer for basic research -- to study when and why organisms become resistant to antibiotics -- is contemplated by the Stanford research team.

###

Mailed September 30, 1970.

#1 Computer at Stanford University Medical Center keeps tab on dangerous bacteria, monitors changes in their resistence to antibiotics, and helps facilitate therapeutic decisions. Here Miss Adrienne Kataoka, a medical technologist, carries on dialogue with the machine, while Edward Russell, Jr., a medical student, and Dr. John Petralli, a research associate, review report. The new application of the computer is expected to improve reliability of antibiotic sensitivity testing, and to contribute to improved diagnosis, timelier treatment, and far less medical paper work. 9/70

#2 Antibiotics (small dots) added to bacteria culture will produce a clear ring or inhibition zone. By measuring the diameters of these rings, technicians determine the effectiveness of each of the antibiotics against the micro-organism in question. This standard technique, which requires precision, is now subjected to quality control by a computer which has eliminated errors occurring frequently in the past. The computer application is part of a new program at Stanford University Medical Center to give doctors reliable information about which antibiotics they should use to treat specific infections in their patients. 9/70

FOR IMMEDIATE RELEASE

CHICAGO -- A Stanford University medical research team has linked a widely used anesthetic with a high incidence of postoperative kidney disturbance.

The anesthetic is methoxyflurane, a pleasant-smelling nonexplosive vapor, sold in the United States under the trade name Penthrane.

In half of the patients, studied by the researchers, the kidney disturbance was severe enough to produce clinical symptoms. In the remaining patients it could be detected only by biochemical tests, they said.

Despite the difficulties this anesthetic appears to have caused in the postoperative management of the acutely affected cases, all patients eventually recovered.

This is not the first time that the anesthetic (by some estimates administered to as many as two million patients per year) has been reported to cause problems in kidney function.

In 1966, similar findings were reported in the journal Anesthesiology by a research team of the Veterans Administration Hospital in White River, Vt. The findings at that time were duly noted but several questions remained unresolved. Other reports of the same phenomenon have been published in other journals from time to time, but the Stanford work is, perhaps, the first well controlled and continuing study, according to the researchers.

The study was carried out at the Palo Alto Veterans Administration Hospital by Dr. Richard I. Mazze and Dr. Stephen H. Jackson, both assistant professors at the Stanford University School of Medicine. They reported their findings at the fall meeting of the American Society for Pharmacology and Experimental Therapeutics held recently at Stanford. A report of that presentation appears in the September 21 issue of the Journal of the American Medical Association.

In the study, 22 patients receiving mostly abdominal surgery were randomly given two different anesthetics. Ten of the patients were given halothane and 12 methoxyflurane. None of the patients had a history of previous kidney disease, and the groups were comparable in sex, weight, and age range.

According to Dr. Mazze, patients who received halothane had a normal postoperative course.

In contrast, all patients who had been given methoxyflurane showed signs of kidney disturbance.

The six patients, who became more seriously ill than the rest, had the greatest biochemical abnormalities, suffered dehydration and weight loss, and took as long as two months to recover completely, Dr. Mazze reported.

"The findings are cause for concern, and additional evaluations of methoxyflurane are underway," he added.

STOCKTON -- When migrant farm workers and their families in San Joaquin County go for a health checkup, they go to a fiesta.

The fiesta is one example, among many, of community involvement designed to attract people who will not go too far out of their way to seek preventive medical care.

All across the county people are responding to operation "San Joaquin Health Checkup" conceived by the San Joaquin Medical Society and Foundation for Medical Care and local poverty area leaders. It is funded by the California Regional Medical Programs.

The program is intended to help bring the benefits of medical care to poor urban families and migrant farm workers in the county, and to combat health ignorance by involving people in active project participation.

"One of the most serious deficiencies in the present health system is absence of a sense of participation or control of their fate by patients seeking health care," program officials are quick to point out.

Not all health checkups, however, are organized in connection with fiestas. The program depends on improvisation for effectiveness, and in the case of urban poor families, health examinations are being provided in connection with church services.

Goal of the health checkup is to screen 3,000 persons annually for the next three years as the initial step to bringing them into the local health care system.

San Joaquin County is part of California Regional Medical Programs, (CRMP), Area III, which covers 11 counties extending from the coast to the crest of the Sierra in mid-California. Stanford University School of Medicine coordinates CRMP for Area III which has a population of 2.5 million and about 3,600 physicians, 14,000 registered nurses, and 75 registered hospitals. Area III provides a study in contrasts--economic affluence and plethora of health personnel and facilities in some locations and sizable pockets of rural and urban poor in migrant camps and major cities.

The project provides multiphasic screening and follow-up care, long considered the backbone, but often the lacking ingredient, of preventive health care efforts. Activities are planned through committees in poverty communities so that multiphasic screening can become a natural component of social planning, according to the program coordinators. The program also relies on local health organizers familiar with each community, who become natural messengers for community participation.

The program had its trial run in August, when health checkups were given to residents at Matthews Road and Harney Lane labor camps near Stockton. Accompanied by the sounds of Mariachi bands, refreshments, and food--provided by the local communities--the health checkups attracted large crowds, and some 400 persons benefitted from them medically.

-more-

Dr. William C. Fowkes, assistant professor of medicine and Area III Regional Medical Programs acting coordinator, terms the favorable response "a result of tailoring health services to the life styles of those who receive them."

Multiphasic screening employs tests by which patients are screened for more than one disease or abnormality at a single visit. Tests are carried out by a staff of bilingual doctors, registered nurses, and technicians in a mobile unit made up of three trailers, usually parked inside the camps or near neighborhoods.

Patients receive tests for lung function, blood pressure, visual acuity, heart function, X ray, and blood and urine. Women get routine "Pap" tests for detection of cervical cancer.

When the testing is over, persons who need medical attention, are sent to doctors in the medical community for follow-up diagnosis and care.

The entire battery of tests costs about $34 per patient, covered by a grant from the Division of Regional Medical Programs of the Department of Health, Education and Welfare.

Facilities and personnel for the actual testing and organization of the program are provided, under contract, by the Health Facilities Foundation-Health Testing Services of Berkeley, a nonprofit organization with previous experience in screening programs for cannery workers in the valley.

The proposal to set up a program of multiphasic screening stems from the long-standing concern of San Joaquin County doctors with the problem of bringing medical care to residents of migrant camps and the "poverty pockets" of south Stockton.

Nearly 20 per cent of Stockton's population lives in neighborhoods where family income is at the poverty or near poverty level, according to Regional Medical Programs figures. These neighborhoods are only partially involved in organized community activity, and are burdened by inequities and inadequacies in the delivery and distribution of health care services.

"We want to reach the disadvantaged on a professional basis before they come to us under the pressure of crisis of illness," said a San Joaquin Medical Society spokesman.

"We have been involved for several years in the operation of migrant camp clinics, but we need a method to evaluate the health needs of all camp residents in a way that will bring them to care more effectively, making better use of services that our physicians are willing to provide."

Health problems among the urban poor require a different assessment, according to the Medical Society official. Their health is interwoven with problems of housing and employment, which create a climate of frustration that must erupt, bringing with it demands that are then met in a fragmented, hurried, costly and ineffectual manner.

"The poverty community is, of course, acutely aware of these existing problems, and we have met with their representatives to develop a cooperative action program," he said.

Organizations which helped formulate the model program included the Black Unity Conference, the San Joaquin County Health Department, San Joaquin General Hospital, the Stockton Community Action Council, the Stockton Chamber of Commerce, Mexican-American Political Association, South Stockton Parish, Stockton Unified School District, and many others.

Project proponents hope that mobile multiphasic screening will demonstrate techniques adaptable to other communities and populations inside and outside California. But they are also cautious to point out that it may not solve the health problems of south Stockton or of the agricultural migrants. In fact, it may highlight them by pointing to unmet needs and by increasing the demand for services.

Said Michael S. Muldavin, director of the Health Facilities Foundation: "Preventive care demands an aggressive program of education in the value of early detection of disorders that may develop into cancer or other disease.

"But for the most part, people will not go too far out of their way to seek preventive care.

"The climate of the ghetto or the migrant camp does not call for lectures on medical care. It does call for an opportunity to become involved in group action--to learn about preventive medicine and continuing care by doing something about it." And this is the exciting part of the entire San Joaquin Health Checkup.

STANFORD --The linear accelerator was credited Saturday for having liberated medical scientists to further work in radiotherapy and to develop life-saving treatment methods for cancer patients.

One of the most dramatic gains, made by the adaptation of the accelerator for medical use, has come against the malignant lymphomas, particularly the formerly fatal Hodgkin's disease.

Since 1962, according to Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology at the Stanford University School of Medicine, 74 per cent of all patients with various stages of Hodgkin's disease treated at Stanford have lived five years or more. The figure nationally was 36 per cent in 1960 before the advent of the medical linear accelerator developed simultaneously by research teams at Stanford and in England.

"The figures do not tell the full story," Dr. Kaplan said. "In the past three years further improvements in technique have been introduced which give strong indication we will push those survival figures in most stages of Hodgkin's disease into the 80 to 90 per cent bracket within a short time."

Dr. Kaplan made the prediction at the dedication of the $1 million Paul A. Bissinger Radiation Therapy Center at Stanford University Medical Center. Dr. Kaplan, a 1969 Atoms for Peace prize winner, has pioneered in the development of the medical linear accelerator.

He said the medical linear accelerator has now become the "work horse" of modern major radiation therapy centers, and the achievements which it has made possible have completely altered the image of radiation therapy once thought by many doctors as having essentially no curative potential.

"Radiotherapy now stands right alongside surgery as the major method for the permanent cure of many kinds of cancer," Dr. Kaplan said. "And at least 50 per cent of all cancer cases, including those in advanced stages referred to modern radiotherapy centers, have a substantial chance for permanent cure."

Major credit for the progress, according to Dr. Kaplan, can be claimed by physicists who developed the linear accelerator.

"We feel they are to be congratulated on this occasion for the very major contribution they have made to medicine," Dr. Kaplan said. -more-

It was Dr. Kaplan who met with three other Stanford men, who formed the Microwave Laboratory Committee in the early 1950's, to look into the possibility of adapting the linear accelerator for use in radiation therapy. The committee members were Drs. Frederick E. Terman, Leonard I. Schiff, and Edward Ginzton, then laboratory director and presently board chairman of Varian Associates in Palo Alto. Work on the actual design and construction of the first medical linear accelerator was undertaken by Dr. Ginzton.

With funds from the National Cancer Institute, the American Cancer Society, and the Office of Naval Research, the new machine was completed and was installed for clinical use in January, 1956 in the old Stanford hospital in San Francisco. It was the first such device in the western hemisphere.

In addition to Hodgkin's disease, Dr. Kaplan cited other types of cancer, previously beyond the scope of the radiotherapist, which can now be treated by application of the accelerator:

Cancer of the prostate: "One of the deep-seated tumors radiotherapists thought it was difficult to treat has turned out to be a pleasant surprise. Results to date show a five-year survival for 55 to 60 per cent of the Stanford cases. These results have made the technique widely accepted as a method of achieving cure, and in many cases, long-term control of the disease."

Cancer of the urinary bladder: "A very prevalent and important kind of cancer, it was virtually untreatable because standard X-ray techniques caused severe skin reaction that made the treatment at appropriate doses intolerable. Today, with the aid of accelerator beams, cure rates of five years in 25 to 35 per cent of the cases have been achieved."

Retinoblastoma: "A rare type of eye tumor, it has often been treated surgically by removal of the eye. Today in early cases, it is no longer necessary to remove the eye because the results of radiotherapy are excellent."

Ovarian Cancer: "Numerically, cancer of the ovary is very important in women. Techniques developed through use of the linear accelerator for the first time offer hope of cure for patients with primary inoperable types of ovarian cancer.

"The same can be said for cancers of the testes that have spread to lymph nodes in the abdomen and beyond into the thorax and neck. Five-year survivals of 75 to 95 per cent have been recorded for such patients."

(ADVANCE) FOR PM RELEASE SATURDAY, SEPTEMBER 12, 1970

STANFORD -- The Stanford University School of Medicine Saturday announced it is investigating a new cancer weapon, potentially more effective than conventional radiation therapy methods.

Disclosure of the new research was made by Drs. Malcolm A. Bagshaw and Henry S. Kaplan at the dedication of the new $1 million Paul A. Bissinger Center for Radiation Therapy at Stanford University Medical Center.

The new project has grown out of low-temperature physics investigations by Stanford Physics Professors H. Alan Schwettman and William M. Fairbanks. It will be aided by the construction of a new large-scale superconducting linear accelerator for electrons, the first of its kind, now near completion at Stanford's High Energy Physics Laboratory.

The new machine, according to Dr. Bagshaw, produces a stream of negative subnuclear particles called pi mesons which, if directed at cancer tumors, should theoretically be 6 to 12 times more effective for treatment than other types of radiation, including X rays and gamma rays.

Dr. Bagshaw made the disclosure in his talk on the future work in cancer therapy at Stanford. He is professor and head of the Division of Radiation Therapy. Dr. Kaplan, professor and chairman of the Department of Radiology, has pioneered in the development of linear accelerators for medical uses.

The immediate plan, according to Dr. Bagshaw, is to utilize the High Energy Physics Laboratory superconducting accelerator to produce pi mesons, and to study methods that will permit the adaptation of the device for clinical application in cancer patients.

Based on this work, a prototype of a superconducting linear accelerator for hospital use will be built, he said.

Dr. Bagshaw explained how pi meson radiation works: "When a negative pi meson penetrates into tissue and comes to rest, new phenomena occur which have no counterpart with more conventional types of radiation. These phenomena are primarily responsible for the attractiveness of negative pi meson treatment for cancer."

The negative pi meson is an unstable particle, and when it reaches the end of its path in tissue its negative charge is captured by a nucleus of a carbon, nitrogen, or oxygen atom, which are normal constitutents of all tissue.

When captured, part of the extremely high energy of the pi meson appears in the form of alpha particles and protons of very short range and high ionization density.

The pi meson produces little ionization, or tissue damage, on the way in. But when the pi mesor stops and is abosrbed in the tumor, it deposits a great deal of destructive energy in the tumor mass, Dr. Bagshaw said.

Getting the pi mesons to stop in the tumor will be done by altering the entering kinetic energy of the mesons, either through computer-controlled machine adjustment or by using shielding which slows the pi mesons to the desired entrance velocity.

In addition, the radiation produced by the destructive energy of pi mesons in the tumor area can be readily "seen" by gamma ray detectors. This should permit doctors to pinpoint the region in the patient in which the cancer's destruction will occur.

Accelerator energies of about 500 million electron volts are needed to produce the 100-million-volt mesons needed for cancer therapy. These have so far been available only from extremely large and expensive machines such as the $55 million meson factory built at Los Alamos, which is planning extensive clinical use of its facility.

The new Stanford superconducting accelerator suggests the possibility of much smaller machines costing about one-tenth as much, which could be built into hospitals and medical centers.

"Radiotherapy is on the threshhold of a general movement into the utilization of different types of penetrating energy such as neutrons, protons, and negative pi mesons for the treatment of cancer," Dr. Bagshaw said.

The cost of these new radiation sources will be 10 to 20 times greater than those currently in use, but their ultimate payoff in improvement of cancer cure rates should more than justify the expenditure, he added.

Dr. Bagshaw emphasized that the possible medical use of pi mesons is still in the preliminary stage, and that further development will depend on allocation of federal funds now being sought.

STANFORD -- Research papers by Stanford University psychiatrists and psychologists won two major awards at the American Psychological Association Convention, which met in Miami this week.

The awards, presented by the Association's Division of Psychopharmacology, carried research grant funds and cash prizes totalling $1,000 and $800. The papers won on the basis of the quality of the research done.

Dr. H. Keith H. Brodie, assistant professor of psychiatry, delivered the first-place paper, which dealt with a study at the National Institute of Mental Health on drug therapy for the severely depressed patient. In 86 patients hospitalized because of depression, Dr. Brodie and co-authors Drs. William E. Bunney, Dennis L. Murphy, and Frederick K. Goodwin of the NIMH, found that the drug of choice for depressed patients with a history of mania (periods of grandiosity, euphoria and extreme elation), is lithium carbonate. For depressed patients without a history of mania, imipramine, the researchers found, is the drug of choice.

Dopa, a third drug tried, caused depressed patients who had had manic states to worsen. It had no effect at all on strictly depressive patients. Imipramine also caused sometime-manic patients to worsen, although the effective drug for them, lithium carbonate, like dopa, had no effect on strictly depressive patients.

The second paper was delivered by Dr. Harry B. Cohen, acting assistant professor of psychiatry, and co-authored by medical student James M. Ferguson, doctoral candidate Steve Henriksen, and Drs. Jon M. Stolk, Vincent P. Zarcone, Jack D. Barchas and William C. Dement.

Their paper dealt with a study of the role of a brain chemical called serotonin in the sleeping pattern of cats.

STANFORD -- Dr. Jesse L. Steinfeld, surgeon general of the United States, and other noted speakers will highlight the dedication of the new $1 million Paul A. Bissinger Center for Radiation Therapy at Stanford University Medical Center, Saturday, September 12.

The public ceremony marking the official opening of the expanded radiotherapy facility will be held at 10 a.m. in the Cooper Courtyard of the Medical School.

Dr. Steinfeld will discuss "Progress and Prospect in Cancer Research." A noted expert in cancer chemotherapy, and former professor of medicine at the University of Southern California School of Medicine, Dr. Steinfeld entered government service in 1968 as associate program director of the National Cancer Institute. He became deputy director the following year, and then deputy assistant secretary for health and scientific affairs of the Department of Health, Education, and Welfare.

The U.S. surgeon general will be preceded by Dr. J. E. Wallace Sterling, chancellor of Stanford University, who will discuss "Reflections on Radiology's First Accelerator."

Reports of achievements of the past 15 years and on future work in cancer therapy at Stanford will be presented by Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology (who conceived the use of the linear accelerator for medical purposes) and Dr. Malcolm A. Bagshaw, professor and director of the Radiation Therapy Division.

Following the talks, Dr. John L. Wilson, acting dean of the Medical School will present the building to W. Parmer Fuller, III, president of the University's Board of Trustees.

An open house for the public will be conducted after the dedication ceremonies.

The new building has been named in honor of the late Paul A. Bissinger, Sr., prominent San Francisco businessman and civic leader.

Mr. Bissinger, who died of a stroke in London October, 1969, had been successfully treated for cancer of the lymph node system at Stanford in 1967. Following his therapy in the crowded, overtaxed facilities, he contacted other former cancer patients and interested associates and organized "The Friends of Radiology" to raise funds needed to expand the therapy program.

-more-

At the time The Friends of Radiology group was formed, Mr. Bissinger said, "If we are able to help financially with the expansion of facilities at Stanford, thus giving more cancer victims the chance we were given, perhaps our debt of gratitude will partially have been paid."

The group raised nearly $450,000 which has been matched by State and Federal funds. The expansion includes a new building which houses administrative offices and personnel and patient support facilities such as examining rooms. The present quarters of the Radiotherapy Division have been remodeled to accomodate two new medical linear accelerators, bringing to three the number of such machines in the department which produce high-energy X rays for treatment of cancer.

One of the new models will replace an older prototype accelerator which has been in use since 1956, when it was first adapted for medical use by Dr. Kaplan.

The new building and equipment will allow for treatment of 25 to 30 per cent more patients. At present 2,400 treatments for various types of cancer are given monthly at Stanford with existing equipment and personnel operating 10 hours each day. The daily patient load averages 141 persons and over 1,400 new patients are treated each year.

The new facility will also enhance Stanford's training programs in radiotherapy. The National Institutes of Health have established in the Department of Radiology one of the first comprehensive programs for the training of fully qualified radiotherapists. Approximately 10 per cent of all residents in radiotherapy in the United States are trained at Stanford.

Architect for the project was the firm of Howard A. Friedman and Associates of San Francisco. Morris Daly of Burlingame was the general contractor.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

(ADVANCE) FOR PM RELEASE FRIDAY, OCTOBER 30, 1970

STANFORD -- A computerized blood bank system, which can give medical personnel instant access to information about donors and related clinical data, has been designed by Stanford University scientists.

The computer, on command by a blood bank clerk, can scan the list of available donors, choose those with just the right blood type, and print out the names of people to be contacted in an emergency or when the blood bank's inventory is low.

Presently many blood banks use computers for similar storage and retrieval of information. But all of these systems must be operated by persons with extensive computer experience and training.

The Stanford system, based on a new computer language called DIRAC (DIRect ACcess), can be operated, updated or expanded by anyone without previous experience in computer programming.

Development of the computerized blood bank system was announced Friday at the annual meeting of the American Association of Blood Banks at the San Francisco Hilton Hotel. Authors of the report included Dr. Paul Wolf, associate professor of pathology and director of clinical laboratories and the blood bank at Stanford University Medical Center; and Drs. Herbert R. Ludwig and Jacques Vallee of the Stanford Computation Center.

Dr. Wolf stated that "use of this system developed by Stanford's Computation Center, has made it possible to conceive a program of considerably lower cost than currently available in other implementations across the nation."

He said the computer is expected to reduce the paper work in the blood bank, and improve inventory control.

"Such control is a serious nationwide problem in the blood bank field," Dr. Wolf said. According to the San Jose American Red Cross, 18 per cent of the blood supply in banks becomes outdated before it is used.

The figure is 10 per cent in the small Stanford blood bank, but the use of the computer in keeping accurate inventory is expected to reduce the loss to less than five per cent. This could be done by keeping a reasonable supply on hand, and making a call for donors only when new blood is really needed, he added.

Another area in which the new system will be truly useful has to do with preparing the many fractions of blood that are used for patients--platelet concentrates, packed red cells, plasma, cryoprecipitate for hemophilia, white cell poor blood, and other components.

And there is the problem of crossmatching blood, only the first step in transfusion. If the patient has a common antibody that most donors' blood will react against, only a handful of donors may be useful. Who are these people and how may they be contacted quickly?

"The computer can identify specifically matched donors and recipients, thus increasing the chances for survival of the patient," Dr. Wolf said. Dr. Wolf hopes the new computer system to be operational in the Stanford hospital blood bank before the end of this year. ###

FOR FURTHER INFORMATION CONTACT: Polly Downing 415: 321-5310

STANFORD -- A new pilot program to relieve the doctor shortage is underway at Stanford University Medical Center. It will prepare registered nurses to aid physicians in providing for family care in areas where it is not available, and will allow for a better distribution of the physician's time.

The program is one of the first in the nation to focus on training nurses to give primary care to families as a whole. Other nurses programs concentrate on training for specialized areas, such as in pediatrics and anesthesia.

The project will provide one answer for communities where a physician is often many miles away, or in urban areas where the demand far exceeds the available supply of doctors.

Each nurse studying in the program comes from communities where medical care is in short supply. She comes with strong community support behind her. She has been selected by the community or health center where she is already working and they are paying her way. A return place is assured for her. Stanford provides no funds for any part of the project, but doctors and nurses at the Medical Center contribute teaching time.

The women, who are all registered nurses, are already functioning in these communities in much the same role that they will return to; the program will give them additional skills or knowledge to let them act as extensions of physicians.

The program will help the nurses identify the limits of what they can appropriately handle and when the doctor must be reached immediately. (For example: does the patient have acute appendicitis, or is the trouble more routine?) Whatever the difficulty, the nurse can go ahead with the preliminary findings or treatment, order the lab work done, describe the urgency to the physician, make referrals and in general deal with the problem at hand.

In other situations she will continue the care of the patient. She will actively share in delivery of babies, geriatrics and pediatrics, in giving emergency treatment, whether in the patient's home or in the office, as well as routine patient visits with general practitioners in community health centers or offices.

The program began September 28, with five nurses in training. It is of four months duration at Stanford with a one year follow-up after the nurses return to their home position. The first three months are a swift-paced combination of classes and practical clinical experience at Stanford University Hospital, the Palo Alto Veterans Administration Hospital, the Valley Medical Center, the East Palo Alto Neighborhood Health Center, the Palo Alto Clinic, as well as facilities of various public health agencies.

There is one month of field placement, which will duplicate as closely as possible the situation that the nurses will be returning to. Here, each nurse will work under a doctor's supervision and direction.

-more-

The project, set up on a feasibility study basis, is a joint venture of the Department of Community and Preventive Medicine and the Area III, California Regional Medical Programs. Stanford University School of Medicine administers the Regional Medical Program in 11 counties in mid-California.

Mrs. Jeanne LeBrun, associate coordinator for Area III of the California Regional Medical Programs, and clinical lecturer, Department of Community and Preventive Medicine, directs this project. Also closely involved in the program's development is Mrs. Mary Alderson, R.N., Area III's nurse coordinator, Dr. William Fowkes, Area III acting coordinator, and Mrs. Ludmila Davis, R.N., director of the operating and emergency rooms at the Hospital. It is their hope that a strong, continuing program will emerge as one answer to what Stanford can do toward alleviating the doctor shortage.

What these nurses are to be called, however, has met with a variety of views. "Nurse Practitioner" seems to have the most approval at the present time, although "Nurse Physician's Assistant" is a close runner. As one nurse commented, "People tend to expect a different type of leadership when a person has a new title."

Development of the program has been aided by a new California law allowing the State Board of Medical Examiners to set standards for medical assistants.

One of the five women in the program is Comfort Ekpunobi from Biafra. She is also an English-trained midwife, in addition to being a registered nurse. She has most recently been at the East Palo Alto Neighborhood Health Center, and will return there.

Kay Ortman and Jane Curtis are from rural Idaho and will return to work under the supervision of two physicians who function out of Council, Idaho, but whose territory covers over 100 miles. Mrs. Ortman, married to a forester, has done community mental health counseling and general staff nursing. Cambridge, Idaho is in the process of building the area's first professional clinic in which she will work. Mrs. Curtis has been director of nursing in the community hospital in Council. She is the wife of the superintendent of schools there.

Lois Sykes has been working in Livingston, California. Her training here is sponsored by the new health center set up by the entire Livingston community, with the help of Stanford University Medical Center's Department of Community and Preventive Medicine. Livingston is in Merced County, where there is roughly one physician for 2,000 people, She will return to the Livingston Clinic.

A nurse from the Stanford Hospital operating room, Ann Keeler, is the fifth student enrolled in the course. She also functions as a liaison person to aid the students in orientation to the Medical Center.

FOR FURTHER INFORMATION CONTACT: Mary M. Griffith 415: 321-5310

STANFORD -- Carl P. Sheaffer, a Stanford University heart transplant patient, Monday (Oct.26) celebrated the second anniversary of the operation that returned him to a vigorous life.

In 1968, Sheaffer, who is now 56, was the seventh person to become a recipient in a series of heart transplant operations at Stanford which now numbers 26. He is the first of Stanford's heart transplant patients to reach the two-year survival mark.

Eight other Stanford patients besides Sheaffer are now surviving, seven of them out of the Hospital. Their survivals range from 20 months to 11 days. The latter is a patient who received a new heart Oct. 15, 1970.

Monday the other surviving patients gave a party at the Hospital for Sheaffer and his wife Effie to celebrate the anniversary.

The event contrasted sharply with the life Sheaffer led in the decade prior to 1968, when severe heart disease forced him to retire and give up even mildly strenuous activity.

Sheaffer was a plumber by trade and a fisherman and hunter.

In 1959, he moved his family from Dillsburg, Pa., to Winchester Bay, Ore., mainly because Oregon's waters and forests have much to offer an outdoorsman. But his failing heart prohibited him from taking full advantage of the new environment.

All this changed after the transplant operation. For the past year and a half, Sheaffer has been making frequent trips back to Oregon from the San Francisco Bay Area where he and his wife now live. Last spring's expedition "up the Umpqua River for steelhead" lasted six weeks. "You have to go for a long time to get results," he explains.

Summer and early fall trips are for Chinook salmon. These usually weigh from 10 to more often 30 or 32 pounds. Late fall is for elk, and Sheaffer is preparing now to leave for Scottsburg, where he will join his friend and hunting partner, Howard Rubin for the season.

Grateful to be restored to the activities he most enjoys, Sheaffer says it's just like "really living" again.

The fisherman cures the salmon himself. He gives them away to friends because smoked fish are too salty for a heart transplant patient's diet, which is restricted in animal fats as well as sodium, and sometimes in calories.

Exercise is the other half of the prescription for all the patients. Sheaffer works out (swimming, weight lifting, biking) for two to three hours each day when he is in this area, and he follows a regular regimen of walking and biking when he is in Oregon, to supplement "the good exercise you get when a fish is on the line."

The Sheaffers, who have been married 37 years and have five children and nine grandchildren, attended the wedding of their youngest child in July. He is a son, William E. of Reedsport, Ore. The others are Dorothy Jane Buffington of North Hollywood, Calif.; Shirley May Buffington of Franklintown, Pa.; Carl F. of Franklintown; and Ronald E. of New Cumberland, Pa.

STANFORD -- A fresh approach is being taken at the Stanford University Medical Center on the question of physician assistants training, which medical experts believe to be one of the most far reaching and fastest growing concepts in medical care delivery to come along in decades.

The new program to start in January, is directly aimed at increasing and upgrading paramedical aides -- a concern that is receiving increasing attention from both the Government and hospitals all over the country.

This program grew out of two earlier ones. It is committed to involving minorities, as was one of the previous programs, which had details worked out by William R. Stone and Moses Thomas of the Medical Center's minority relations office.

Another tack had been pursued by Dr. Donald Laub, chief of plastic and reconstructive surgery, who planned to get a program underway involving the use of medical corpsmen.

Dr. Michael Dennis, a surgeon, is now heading up the projected physician assistants program. A Harvard graduate in 1964, with an M.D. from the University of Florida in 1968, the 28-year-old Dr. Dennis says that he has been concerned since his college days with the problems of delivery of health care.

New impetus was also given with the passage of a state law authorizing the State Board of Medical Examiners to set up training programs and standards for physician assistants. This new law puts California in the vanguard of a nationwide effort to meet the growing doctor shortage. The law will be very helpful, if not crucial, to the efficient use of the graduates of the Stanford program.

Dennis feels strongly physicians themselves should take a more active leadership role in setting up programs designed to extend this care. "Otherwise, the problems -- and the demands from all sides -- are only to get worse."

He is designing the program to have two self-contained phases, the first being the equivalent of medical corpsman training. Drawing heavily on manuals and methods already set up for turning out medical corpsmen, the aim is to create in a 12-month period a civilian medical corpsman who can be allowed to handle a number of situations, particularly in the emergency room.

The candidates for this course, which will be "tough and realistic," can be high school graduates or with some additional training or college, who score satisfactorily on a battery of tests, have good recommendations, and who demonstrate a real motivation to be directly involved in the delivery of health care.

-more-

Dennis noted the availability of candidates for both phases. "There are a lot of bright, dedicated men who have had medical corpsmen training, but because of the structure of medical education, they just haven't been able to continue their medical career, and with the younger fellows, financial difficulties and continuing discrimination have put up real entrance barriers to their even getting started." He noted also that there are a number of nurses who are eager for more responsibility who have already applied. In both phases there are, accordingly, many qualified candidates, Dennis stressed.

He also sees the initial phase as a two-way testing ground -- a chance for a young man to really learn what the practice of medicine is all about, and a chance for the staff to observe his potential.

The second phase of the program is conceived of as a 15-month course: four months of formal teaching, and 11 months of practical application and learning, working with doctors. Prerequisite for the course would be completion of the program's initial phase or the equivalent of medical corpsman or nursing training.

The classes, which will be at Stanford, are aimed at developing "competency" in recognizing and aiding in the treatment of about 50 of the most common diseases. The aim for the remaining period is for these men to work with doctors in surrounding communities or in other hospitals throughout northern and central California. Dennis noted the potential for this kind of cooperation looks very promising.

He said he has already sent out a questionnaire to a sample 1600 doctors, asking them if they could use such an assistant, and if they would be willing to train these men on a "preceptor" basis. (A preceptor works something like the old idea of apprenticeship, except that as a preceptor, the doctor always remains in charge. It would be up to both the doctor and his charge to develop "excellence." The expectation is that the doctors would continue to use these assistants as their aides after the training has ended.)

The response from the doctors has been great, Dennis said. "The majority of them are writing in that they'll be glad to help." He noted the doctors are general practitioners and that an additional benefit from the program will be to bring them into contact with Stanford. In turn, he feels Stanford will benefit from having an involvement with general family medicine practitioners which it does not now have.

The California Board of Medical Examiners will set up guidelines to determine what the graduates of the course can actually be allowed to do.

However, Dr. Dennis hopes that these aides will eventually be able to assist in the delivery of babies and to cover for doctors in nursing homes by making some rounds with the chronically ill patients and so keeping the doctor informed of all developments in their care.

-more-

Dennis also believes that graduates should be directed toward areas where they are most needed, such as East Palo Alto and rural communities in California where patient needs far exceed doctor supply. "This program isn't for the San Francisco doctor," Dr. Dennis allowed. He expects to work with the Department of Community and Preventive Medicine, chaired by Dr. Count D. Gibson, Jr., in placing the graduates in needed areas.

Dennis sees the whole program as having several goals: the primary one is to expand the delivery of family health care. Other aims are to give qualified minority people real upward mobility in an area where they are greatly needed and where they haven't been able to enter, and to determine if the rapid learning military corpsman situation can be duplicated in a civilian setting.

The entire program is an expensive one, both because of the training involved and because stipends are needed, especially for those in the second phase. Current candidates are older men and most of them have families, so a liveable stipend is crucial.

There are already 210 applications for this group, of which only a maximum of 30 will be chosen. If new funding plans fail, only eight will be selected for the initial January class.

The first phase -- that of the civilian corpsman -- has not been funded. However, an overall package for the two programs is being sought. Dr. Dennis expressed a cautious hope that both programs will get underway after the first of the year.

He projects an ideal of $11,290 per person for both phases. This figure reflects a total budget of administrative expenses, teaching consultants, space, material, transportation, communication and stipends. He expects this initial high to decrease after the program is in progress.

STANFORD -- Richard J. Cope, a 45-year-old retired engineer from East Patchogue, Long Island, New York, received a transplanted heart in an operation performed by Dr. Norman E. Shumway and his team today at Stanford University Medical Center.

The patient is accompanied on the West Coast by his wife, Adelaide, and her mother, Mrs. Adelaide Carlson. The Copes have a son, Richard.

Cope becomes the 26th heart transplant patient at Stanford. Of the nine who are surviving, eight have been dismissed from the hospital and are living essentially normal lives. One patient, Carl Sheaffer from Winchester Bay, Oregon, will mark the second anniversary of his transplant operation on Oct. 26.

STANFORD -- Dr. Howard Bertram Burchell, professor of medicine and chief of cardiology at the University of Minnesota Hospitals in Minneapolis, will give the seventh annual John Kent Lewis Memorial Lecture Monday, October 19, at Stanford University School of Medicine.

His talk, "An Inquiry into Some Cardiologic Taboos," will begin at 4:15 p.m. in Room M-106 of the medical school.

Dr. Burchell has devoted his professional life to the study of the heart and circulation. Beginning with "Adjustments in Coronary Circulation After Experimental Coronary Occlusion," his Ph.D. thesis at the University of Minnesota in 1940, Dr. Burchell has published numerous papers on applied hemodynamics and electrocardiographic studies.

He has been editor-in-chief of the highly respected medical journal, Circulation, since 1965, and is a past chairman of the research committee of the American Heart Association. In 1958 he received the AHA's Award of Merit for his contributions to cardiology and services to cardiologic research.

A native of Athens, Ontario, Canada, Dr. Burchell received the M.D. degree from the University of Toronto in 1932. Before assuming his present academic post in 1968, he was for many years a consultant and member of the faculty of the Mayo Foundation.

The John Kent Lewis Lectures at Stanford are dedicated to the memory of a 1922 medical alumnus who became chief of the Stanford Medical Service at San Francisco General Hospital in 1949, and was a noted pioneer in research on the heart. He died in 1961.

STANFORD -- The Palo Alto City Council has granted Stanford University Hospital a permit to build a heliport for emergency arrivals. The request was approved by the Council last night (Tuesday, Oct. 13).

The Hospital plans to construct a helicopter pad 700 feet north of the emergency room entrance, on a site providing direct line ambulance access.

Premature infants being rushed to Stanford to be cared for at the Premature Infants Research Center will be among the primary beneficiaries.

Currently, infants are transported long distance by ambulance, or can come only part of the way by helicopter, with a great deal of time lost in transit.

The heliport will complete the link to the hospital, and "cut down not only actual travel time, but the total time involved, because auxiliary vehicles will not have to travel so far to and from connecting points," says Frank R. Vitale, associate director of the hospital.

Dr. Philip Sunshine, associate professor of pediatrics and director of the Premature Infants Research Center, explained that when an infant is being admitted on an emergency basis, a pediatrician usually goes to pick up the child, taking a portable incubator, and other equipment in case respiratory help, fluids, or drugs are needed en route. Since this means a round trip, the closer to the hospital the pediatrician can be picked up, the faster the infant can be admitted.

"These emergencies happen only occasionally, added Dr. Sunshine, "but we want to be ready when they do occur."

The sooner a doctor can reach a tiny infant with portable equipment and get him hospitalized, the less likely the chance of serious damage.

The heliport will also open the way for state patrolmen to bring critically injured victims of highway crashes directly to the Stanford Hospital, if need be, from remote spots.

Design for the landing pad and plans for its use must meet FAA and California Board of Aeronautics requirements.

STANFORD--Traffic accidents--why they happen and how deaths and injuries result from them--are being studied by a multidisciplinary team at Stanford University.

Over the course of six months, these professionals, including orthopedic surgeons, pathologists, psychologists, and engineering specialists, will visit the scenes of a minimum of 25 accidents in the Bay Area. The first accident investigated by the team was the Golden Gate Bridge approach crash which killed ten people.

From their study the team wants to determine, more precisely than is known now: the elements in nine specific facets of each accident, namely pre-crash-, crash-, and post-crash-phase details relating to human (s), vehicles (s) and environment.

Mainly accidents involving at least one 1968 or later model vehicle will be investigated.

The project is under the direction of David N. Schmidt, engineering physicist. Principal investigator is Dr. Donald A. Nagel, who is professor and head of the Division of Orthopedic Surgery at Stanford University School of Medicine.

The study is supported by the U.S. Department of Transportation. The team will turn in reports and evaluations to the Department's National Highway Safety Bureau, which sets vehicle safety standards.

After examining damaged vehicles at engineering laboratories or storage areas, team engineers will determine not only whether mechanical failure contributed to each accident, but also how effective safety features are in lessening the extent of human injuries and property damage.

A list of safety features now in use includes: the high penetration resistance windshield, collapsible steering column, recessed control knobs, steel reinforcing beams in doors, head restraints, locking seat backs in two-door cars, three-point (attachment) belts, infant seats, interior padding and dual braking systems.

-more-

222--Traffic Accidents

Vehicle dynamics and occupant kinematics will be important considerations in the study. The engineering specialists will "reconstruct" each accident, using the elementary laws of physics to describe the dynamics of the crash. Occupant kinematics refers to how the victims moved or were restrained from moving in relation to the vehicle, and also to occupant-vehicle impacts.

On the medical side, the physicians will be concerned with the nature, extent and cost of injuries sustained in accidents. Dr. Nagel, who brings to the study a background in the physics of injuries, has measured the forces needed to injure bones, and also human tolerance to impacts.

Correlation of his results with the impact forces calculated by the engineers will enable the team to assess present safety requirements and recommend changes. Researchers in previous studies sponsored by the Department of Transportation produced ideas for features which are now in use, such as reinforcing beams for doors, as well as ideas now under consideration, such as air bags to provide cushioning on impact, and fuel containment to the reduce the occurance of post-crash fires.

Dr. Nagel will obtain estimates of the long-term costs of injuries and deaths, to families and to society. "We need to have a look at what two and a half million injury-producing accidents a year mean to us as a nation," the Stanford orthopedist says. "We are trying to understand what happens, and why it happens, so that improvements can be made, not only in vehicles, but in people who drive, and the environments they drive in."

The element of highway design is of major import to the local team. Seeking solutions to design problems in the Bay Area will be one of their primary efforts, according to project director Schmidt. Construction of a median barrier in the approach area of the Golden Gate Bridge was recommended after the crash, he said.

In addition to the specialists mentioned above, psychiatrists, neurosurgeons, plastic surgeons mathematicians, highway designers, traffic engineers and sociologists will also participate.

The Department of Transportation is sponsoring concurrent studies by 15 field teams in other locales around the country.

STANFORD -- The Stanford Medical Students Association will be host to the West Coast Regional Conference of the Student American Medical Association this coming weekend, Oct. 16-18.

Title of the conference is "Medicine For/Against Society."

Registration will be held Friday from 10 to 12 a.m. in the student lounge of the Stanford University School of Medicine. Those in health professions and other interested persons in the community are welcome to attend. There is no charge, but everyone who attends is asked to register.

The weekend meeting begins with a panel discussion Friday afternoon at 1 p.m. Moderated by Stanford medical student body president John Battista, a third-year student, the panel will discuss "Motivation for Change."

Workshops dealing with population, industrial medicine and ecology, problems of rural and urban community medicine, legislative alternatives to the draft, motivation for change, and peace politics make up the schedule for Saturday morning.

Principal speaker Dr. Robert Cooke, who is chairman of the Department of Pediatrics at Johns Hopkins Medical Center, will talk at 2 p.m. Saturday in Bishop Auditorium on "Acceptability versus Efficiency versus Economy in the Delivery of Health Care."

Dr. Count Gibson, professor and chairman of the Department of Community and Preventive Medicine at Stanford, will speak later Saturday afternoon on "The Medical Center as an Institution for Initiating Changes in Medicine."

Charles Payton, national president of the Student American Medical Association and a student at the University of California Medical Center at San Francisco, will also speak at the conference. It concludes Sunday with reports from each of the workshop chairmen in the morning, and tours of Bay Area medical clinics in the afternoon.

Medical students at Stanford had not been participating in the national organization for three years prior to last spring, when they voted to reinstitute a SAMA chapter, and actually to fuse it with the medical student body, an association composed of everyone enrolled in the school. John Battista, and fourth-year student Bob Korns serve as co-presidents of the now double organization.

National SAMA is the sponsor of several community projects in the United States and last summer two Stanford medical students participated in projects in Kentucky and Alabama. ### Mailed 10/13/70.

STANFORD -- Staff changes for two Stanford University physicians and teachers have just been announced by Dr. John L. Wilson, acting dean of the School of Medicine.

Dr. Robert T. Schimke, professor of pharmacology and biology, will become chairman of the Department of Pharmacology, while Dr. David A. Prince, associate professor of neurology, will be acting chairman of the Department of Neurology. Their appointments are effective immediately.

Neurology has been a division of the Department of Medicine. It was recently established as a separate department at the Medical School. This change points up the growth of neurology as a separate discipline, and reflects the increase in neurological research activities.

The 37-year-old Dr. Schimke succeeds Dr. Avram Goldstein who has been chairman of the Department of Pharmacology since 1955. Dr. Goldstein plans to devote more of his time to research and teaching, and also directs the research aspects of a new methadone treatment program for heroin addicts in Santa Clara County.

Dr. Schimke's special field is in developmental and regulatory biology--in particular, synthesis and degradation of specific proteins in animal cells. He has been the recipient of a number of awards and honors including the Charles Pfizer Award in Enzyme Chemistry of the American Chemical Society. He has been associated with the Stanford Medical School since 1966. He graduated in 1954 from Stanford, with an M.D. degree in 1958.

Dr. Prince, 38, received his medical degree in 1956 from the University of Pennsylvania and his training in clinical neurology at the Mt. Sinai Hospital in New York City. His major research interests are in neurophysiology and experimental epilepsy. At Stanford since 1962, he has studied the cellular mechanisms which generate and control epileptic discharge in the brain.

STANFORD -- East San Jose's Chicano community gets little benefit from mental health services it helps support, according to a Stanford University study made public Monday (Nov. 30).

The study was made to find out how relevant are mental health services for urban Mexican-Americans.

It concludes that psychiatric services are "hopelessly inadequate" in meeting the needs of Chicanos in San Jose, and by implication, of many ethnic segments of the American population.

Paradoxically, the study shows traditional psychiatric services do exist, but Mexican-Americans in San Jose prefer their own indigenous therapists to whom they turn with their problems.

"As things now stand, tax funds are being used to build and maintain health services that are irrelevant for Mexican-Americans," the report states. "Residents in East San Jose are having to help pay for mental health services...and get nothing in return."

The study recommends that control for services be turned over to the Chicano community.

Author of the report is Dr. E. Fuller Torrey, formerly of the department of psychiatry at Stanford Medical School and now a special assistant to the director for international activities at the National Institute of Mental Health in Washington, D.C. The report appears in the fall issue of STANFORD M.D., the quarterly magazine of the Stanford Medical Alumni Association.

Dr. Torrey found that the Community Mental Health Center complex in San Jose is more than adequate in terms of meeting specifications set by Washington.

"It is well above average," he writes. "But in terms of fulfilling the needs of a significant minority of its constituents it is hopelessly inadequate."

Mexican-Americans in San Jose constitute 10 per cent of a population of 1 million.

Traditional psychiatric services in Santa Clara County are provided by 150 psychiatrists and psychologists in private practice, general hospitals, Agnews State Hospital, and the Community Mental Health Center complex in San Jose.

The last opened its main center and four satellite health facilities in 1966. Two years later, a fifth facility was opened. Though called the "East Valley" Center, this is a misnomer, Dr. Torrey says, because it is in downtown San Jose and not in the East Valley.

The study shows that of the total visits to the main center in 1968 only four per cent were Mexican-American, under half of what would be expected.

Even the East Valley Center, opened specifically to improve services for Chicanos, had only 11 per cent of patient visits by them during the first nine months.

"Based on need, one would expect Mexican-Americans to overutilize mental health services," Dr. Torrey states. "Their need is indicated by such stress factors as the number of juvenile delinquent referrals, welfare recipients, and dependent children--all of which are disproportionately high for the Mexican-American parts of San Jose. -more-

Dr. Torrey argues that Chicanos cannot use the mental health facilities because they are inaccessible.

There is no way to explain, he writes, why a mental health facility has not been opened on the east side of the city. It is widely understood to have the greatest needs, and the fewest medical psychiatric, and social facilities of all kinds.

"Most of this was known when the location of the satellite centers was decided upon," the psychiatrist claims. "It was also known that the East Valley expected the largest population growth in the county. Yet the centers were placed in more affluent areas."

Dr. Torrey says political considerations, bickering between county and city health departments, and certain members of the Board of Supervisors deliberately blocked allocation of a satellite center to the area where it was most needed.

Language barriers are cited as another reason why more Chicano patients are not treated at the mental health centers. "If a Mexican-American wants to use the facilities, he had better speak good English," Dr. Torrey comments. Of the 120 psychiatrists, psychologists and social workers, only five of them spoke Spanish when the study was done.

In addition there is suspicion among many Chicanos that psychiatry is used to perpetuate Anglos as the ruling class. Cultural differences also exist as to what constitutes mental illness between those who provide care and those who receive it.

"A widely circulated story in the Mexican-American community," Dr. Torrey relates, "concerns the fate of three Mexican-American county employees who went to Washington for the Poor People's March. Upon their return they were ordered to have psychiatric examinations by their superiors."

Dr. Torrey shows that the two mental health resources now used by the Mexican-American community are the "curanderos" (the traditional healers of Mexico and Latin America), and a group of highly respected Chicano community leaders in San Jose to whom people turn with their problems.

There are about 20 such "mental health ombudsmen" in East San Jose, most with regular jobs, who supply mental health services during their off hours. "None of them would consider accepting payment for his services," writes Dr. Torrey. "Many of them are aware that what they are doing is 'psychotherapy' in the Anglo frame of reference. Most of them tend to specialize in certain types of problems except for psychoses."

Dr. Torrey stresses that his study is not meant as an attack on San Jose and Santa Clara County. "The problem began at a higher level," he explains, "when the idea of the Community Mental Health Centers evolved." Its architects perpetuated the dominant-class, dominant-culture, dominant-caste model of mental health services as The Model.

"This works as long as the mental health centers are serving Wellesley or White Plains or Palo Alto. But it is irrelevant when they are to serve Roxbury or the South Bronx or East San Jose," he says.

Dr. Torrey points out that by 1970 some 500 mental health centers will be funded by the federal government. By 1980 the number will be 2,000.

"It is imperative that we learn from our early experiences and modify the model to make it relevant," he comments.

What kinds of changes are needed? Dr. Torrey recommends that control and money for mental health services should be in the hands of a board from the Mexican-American community.

Mexican-Americans may develop and deliver mental health services quite differently than we are accustomed to, he writes. For instance, they might fuse them with social, educational, legal and public health services. They may decide to merge them with services under the model cities program. Or they may decide to place the emphasis on the problem of police relations.

"We should encourage them to conceive mental health services in whatever way it makes sense to them", Dr. Torrey concludes.

FOR IMMEDIATE RELEASE

STANFORD - A Stanford University cancer researcher said Wednesday there is reason to believe guinea pig leukemia may be more related to acute lymphatic leukemia in humans than other animal models.

"This link," Dr. Stanley R. Opler said, "may bear directly on a recent disclosure by the American Cancer Society of a successful vaccination of animals against a specific leukemia virus.

The American Cancer Society stressed the discovery had no present application to human cancers.

But Dr. Opler said new evidence of a link between human leukemia and the blood cancer found in a guinea pig strain has emerged from drug studies at Stanford University School of Medicine and the Stanford Research Institute.

"They have shown guinea pig leukemia responds in a similar fashion to drugs presently used for treatment of leukemic patients," he said.

In addition, pathology studies have indicated that the pattern of acute leukemia as seen in studies of human leukemia and the guinea pig model was strikingly similar.

The results of drug treatment and the similarity of organ involvement and clinical evolution of the disease in humans and the animal model were "intriguing," Dr. Opler said.

Dr. Opler reported his findings last August at the 13th International Congress of Hematology in Munich, West Germany.

In 1969, speaking at an International Symposium on Laboratory Animals, Dr. Opler reported successful vaccination of guinea pigs against leukemia. A report on the symposium will be published shortly by the National Academy of Sciences.

Dr. Opler greeted the recent announcement by the American Cancer Society as providing independent confirmation of the early work.

He discovered the virus which causes leukemia in guinea pigs, and described its unique structure in 1966.

SAN FRANCISCO -- Adoption of a stringent air quality standard -- one that would reduce the level of lead by a factor of three -- was proposed Thursday by a Stanford University Nobel prize-winning geneticist.

Such a standard is the one effective method of protecting the public interest in the face of a poverty of information about lead's effects on health, said Dr. Joshua Lederberg.

"All we know for certain is that lead burdens about three times higher than seen in most urbanites are dangerous threats to life," he said. "Just because intermediate levels of lead are so prevalent, it is impossible to draw firm conclusions about their health effects on the general population.

"We do know that the life expectancy trends in industrialized countries have reached a plateau, and sometimes a small downturn in recent years, and most authorities attribute at least part of this to environmental pollutions."

Dr. Lederberg is professor of genetics. He testified at a hearing on air quality standard for lead held by the California Air Resources Board in San Francisco.

Dr. Lederberg said several other approaches to resolve this issue might be considered. To illustrate his point he suggested that laws might be enacted which would compel the lead industry to insure itself against possible damages that might be claimed in the future by many citizens.

"The industry is gambling that lead additives are harmless," said Dr. Lederberg. "But they will lose very little if they were touting the wrong bet."

He later elaborated that this was not a serious proposal but an example of measures that can be taken toward an equitable resolution.

Dr. Lederberg noted the economic advantages of the use of lead additives averages out to about $5 per capita per year. Most of it is achieved with the first 20 per cent of the lead actually used.

"Our problem is to balance the unknown, but potentially enormous, long-term health hazards against the calculable short-term economic advantages," he said.

STANFORD -- The Stanford University School of Medicine (SAT., Nov. 14) dedicated its new Crossland Laboratory for Audiovisual Learning in Dermatology.

The unique laboratory provides medical students and dermatology residents with teaching machines for studying basic dermatology, including slide facilities, sound on slide, and movie presentations. Portable equipment can be taken into carrels in the laboratory for individual use.

The laboratory was established in appreciation of Dr. Paul M. Crossland, who was a prominent Santa Rosa, California, skin specialist and a dedicated teacher on the clinical faculty at Stanford. Donations from the dermatologist and his wife, his patients and their friends, paid for the laboratory.

Key speaker at the dedication was Dr. Eugene M. Farber, professor and chairman of the Department of Dermatology at Stanford.

Mrs. Harriet Kent Crossland, who painted the portrait of her husband which hangs in the laboratory, attended the ceremonies.

Dr. Crossland had served with the U.S. Navy Medical Corps from 1930 to 1948, a period which included a tour as medical officer in charge on Russell Island, north of Guadalcanal, during World War II. In 1948 he retired from the Navy with the rank of captain and entered medical practice in Santa Rosa.

He entered the specialty of dermatology, and after completing his residency training at Stanford University School of Medicine, joined the School's clinical faculty as a lecturer in 1951. He became a full clinical professor in 1965, and taught until his death at the age of 64 in 1968.

Dr. Crossland was noted as a leading authority on radiation therapy in dermatology. A frequent contributor to the periodical literature in his field, he was also co-author with Dr. Anthony C. Cipollaro of the textbook "X-Rays and Radium in the Treatment of Diseases of the Skin," published in 1967.

STANFORD -- Dr. Luigi L. Cavalli-Sforza, an internationally known expert in population genetics, has been appointed professor of genetics at the Stanford University School of Medicine.

The 48-year-old Italian scientist will assume his new duties at Stanford in February. He currently serves as director of the Institute of Genetics at the University of Pavia, Italy.

Commenting on the appointment, Professor Joshua Lederberg, chairman of the Department of Genetics, said: "Dr. Cavalli-Sforza is Italy's most eminent geneticist. Together with another colleague, Dr. Adriano Buzzati-Traverso, he is largely responsible for introducing modern molecular biology into Italian science."

At Stanford, Dr. Cavalli-Sforza will develop an expanded program for research and teaching human population genetics, Dr. Lederberg said. This subject is focal not only to the general course in genetics for medical students, but also for the University's new interdisciplinary program in human biology.

Dr. Cavalli-Sforza's research has been in two main areas--bacterial genetics, and human population genetics. The earlier work laid the foundation for a better understanding of the genetics of drug resistence in bacteria.

His work in population genetics has focused on the role of chance in determining human evolution, and the development of models and methods for the study of evolutionary relationships between different human populations.

Dr. Cavalli-Sforza has collaborated with Dr. Walter Bodmer, formerly of Stanford, on a new book, "The Genetics of Human Populations," to be published by W. H. Freeman.

Recently, Dr. Cavalli-Sforza has been studying one of the few remaining primitive populations--the pygmies of the central African rain forests.

The Italian geneticist has been a visiting professor at Stanford on several occasions in the past. He was born in Genoa. He received the M.D. degree with honors from the University of Pavia in 1944, and was a research fellow and assistant in genetics at the University of Cambridge (1948-50). In 1954 he went to the University of Wisconsin as a Rockefeller Fellow in genetics. Prior to becoming a professor at Pavia, Dr. Cavalli-Sforza was on the faculty of the University of Pavia, acting director of the International Biophysics Laboratory at Naples, and director of research in microbiology at Istituto Sieroterapico Milanese.

Dr. and Mrs. Cavalli-Sforza are the parents of four children.

STANFORD -- A chance to find out about a nursing career and an opportunity to be hired by local hospitals and extended care facilities is being offered through a new adult education course already underway at Cubberley High School in Palo Alto.

The course, worked out in close cooperation with Stanford University Hospital, El Camino Hospital, the Palo Alto Veterans Administration Hospital, and Palo Alto Unified School District will not give credit, but will provide a semester's worth of training for prospective nurses aides.

Those passing the course are not guaranteed a job, but area hospitals are eager for such trained people, states Marjorie Keys, assistant director, Nursing Service, at Stanford University Hospital.

Of additional value is the fact Dr. Ralph Mason, principal of Cubberley Adult School, has initiated a meeting with the state licensing officials in the field and is fairly certain that students completing the course will be licensed as home nursing aides.

The course is offered Tuesday and Thursday nights, and Saturday mornings, which enables the students to hold down a full-time job, while they are being trained. The course meets Stanford Hospital's requirements and graduates of it, if put on the Hospital staff, will have their in-service training period shortened.

There will be lectures, guest speakers and actual supervised work in medical, surgical and orthopedic wards. Currently, El Camino Hospital facilites are being used; Stanford Hospital will be used for the February term.

The course is taught by Mrs. Florene Poyadue, a registered nurse, who assisted in setting it up. Ability to read and write at a 10th grade level, or a high school diploma if the applicant is under 18 is required.

The actual hospital job that the course leads into will involve assisting nurses in a variety of duties, including giving baths to patients, taking temperatures and blood pressures, admitting and dismissing patients, and performing certain kinds of treatments such as the application of hot and cold compresses. Through it all, the aides will get a good idea of what nursing is all about and if they want to continue in the nursing profession, Miss Keys said.

Possibilities for an additional course that can give credit toward a licensed practical nurse degree are being explored in one of the district colleges.

The current course at Cubberley costs $6 with a $7 text extra. Two uniforms, low-heeled white oxford shoes and a watch with a second hand are the only other expenses.

STANFORD -- Stanford University engineers and physicians are combining their specialties in a unique demonstration project designed to ultimately give one anesthesiologist the capability of monitoring several surgical patients at the same time.

Full application of the new approach is still some time away, but implications are so far reaching that the entire practice of anesthesia may be altered in the opinion of one of the project directors, Dr. J. Weldon Bellville.

A computer system, already at work, takes data directly from the anesthetized patient in the operating room, instantly processes the required information, and returns it to the operating room for use by the attending anesthesiologist.

Use of this modern information processing system is creating an opportunity to attack the principal current problems in anesthesia--the manpower shortage and the need for greater depth and perception in monitoring physiological variables.

The project is a joint undertaking of the Stanford University School of Medicine, and the School of Engineering. It is headed by Dr. Bellville, professor of anesthesia and Dr. Gene Franklin, professor of electrical engineering.

The ultimate goal of the project will be to open up new insights into the entire practice of anesthesia. The result will be the probable emergence of a new type of anesthesiologist--one who not only understands the basic physiology and pharmacology relating to patient care, but also one who uses and understands information processing techniques, Dr. Bellville said.

Eventually, the system may also serve as a model for monitoring approaches in intensive and coronary care, obstetrics, and in the recovery room.

According to Dr. Bellville, the monitoring will enable doctors to know more about patients by remote control than they now know, sitting at the bedside with fingers on the unconscious patient's pulse. The computer will be directed to recognize any disturbance or minute change far more accurately than any other tools currently at hand--which are primarily the anesthesiologist's own ear and eye, stethoscope and blood pressure cuff.

The anesthesiologist's role today is enormously and increasingly important, but without the computer aid, he is still working with tools of another age, Dr. Bellville stated. The anesthesiologists control the vital functions of sensation, consciousness, respiration, circulation, neuromuscular action and metabolism, all under the adverse conditions of preceding disease or malfunction, and immediate surgery.

In effect, the life processes of the patient are under the anesthesiologist's control prior to, during and after surgery, and he must not only anticipate the surgeon's actions and decisions, but also detect changes in the patient and control them, often in a matter of seconds.

-more-

With the new system this crucial role will be backed up and assisted by the computer which processes all physiological information that is being sent in.

The operating room anesthesiologist can ask for one of 16 different computer displays of information; also there is an automatic alarm system and cross checking logic that will instantly indicate sudden change in the patient's condition or any equipment difficulty.

To evaluate the impact of computer monitoring on patient care, cameras are mounted in the operating room. A motion picture camera is adjusted to take one-per-second frame shots of the operating procedures and the anesthetist so that a detailed record is kept.

The detailed pictures will be used for a variety of later studies and to assist in developing new computer programs.

The immediate incoming physiologic data will go by cable to the Sigma 5 computer in the Durand Building, will be processed there and returned in fractions of seconds.

Computer programs have already been developed to process information from various physiologic subsystems--electrocardiograms, analysis of blood pressure and vascular resistance measurements, respiratory mechanics, concentrations of inhaled and exhaled gases and the level of activity of the central nervous system.

Several research associates in the Engineering School have been responsible for this phase of the project. The programming is based on techniques developed in the Department of Anesthesia for computer processing of electrocardiograms by Professor Jobst Von der Groeben.

Anything other than the essential monitoring equipment will be either in a specially constructed control room adjoining the operating room or at the computer center; the operating room equipment will eventually hardly be seen.

Under a separate grant and unrelated project, Dr. James Meindle of the Engineering School is developing integrated circuits for medicine. However, it is expected that through the results of this project, lead wires on the anesthetized patient will soon be replaced by radio transmitters an eighth of an inch square, molded onto the sensors attached to the patient.

At the present time, it is expected that two operations a week will have the computer back-up.

The project is supported by a grant from the National Institutes of Health.

STANFORD--In the belief that new mothers need substantial time to rest and to become acquainted with handling their infants, Stanford University Hospital is restricting maternity visiting hours to two periods a day--an hour and a half in the afternoon, and an hour and a half in the evening.

The general visiting hours of the hospital had been expanded last year for greater flexibility, but the hospital has found that these hours are not in the best interests of maternity patients, explains Miss Lois Williams, assistant director of nursing service.

So, starting this week, maternity visiting hours will be 3:00 to 4:30 p.m., and 7:00 to 8:30 p.m. However, the babies' fathers are not subject to these restrictions and may visit anytime.

Liberal visiting hours will remain in effect for general medical and surgical patients at the hospital. These are, with certain limits which can be set by patients' nurses, from early morning until 9 p.m. at night.

Stanford's Coronary Care, Intensive Care and Pediatric units have their own visiting hours, not related to the general hours or maternity's special restrictions.

Parents of pediatric patients may see their children at any time. Intensive Care Unit visitors are limited to four fifteen-minute periods a day: 10:15 to 10:30 a.m., 1:15 to 1:30 p.m., 5:15 to 5:30 p.m. and 9:15 to 9:30 p.m. Visitors to the Coronary Care Unit may spend 10 minutes of each hour with the patient.

STANFORD -- A small but intense drama of survival is being played in the Stanford University Hospital. The key to its successful outcome is needed from the only people in the world who can help--nursing mothers.

Two babies are making a major fight for their lives in the hospital. In spite of all the excellent care they are getting, they might not survive if they cannot receive human milk, doctors say.

The babies cannot tolerate any formula the hospital can devise, said Dr. Philip Sunshine, associate professor of pediatrics. The only thing they are thriving on at all is the familiar, down-through-the-ages mother's nourishment and the available supply at the hospital is rapidly being used up.

One of the babies, Jason, is five months old. He weighs about nine pounds, which was his initial birth weight. He has had a major intestinal operation, and the blood supply to his intestines is limited. Jason lies in his crib with a bright mobile over it, as though he were in his own nursery room, but he is surrounded by doctors and nurses who know that breast milk is the only thing that will keep him going right now.

Tommy is also five months old, but except for his eyes, which are bright, clear and watchful, he looks newborn. He weighs six and one-half pounds, although he was a full-term five and one-half pound baby. He was born with a major gastrointestinal allergy. He is currently being fed a glucose-amino acid solution through a vein in his neck. Just recently, he has been getting a dilute solution of human milk which is the only food that he has been able to tolerate. Tommy, like Jason, needs a nursing mother's lifeline of help right now.

Dr. Sunshine stressed that the milk donated can be frozen to be used as needed.

However, the problem of keeping a supply of milk on hand is a continuing one, because there aren't ever enough donations, Sunshine said. "We always have babies who have to have this kind of help. Right now it's Tommy and Jason. But it could be any baby at any time. Mothers' milk donations are needed and used constantly."

Mothers who wish to help may contact Barbara Eickworth in the Premature Infants Research Center, Stanford University Hospital, 415: 321-1200, extension 5445. She will give specific instructions as to what to do.

STANFORD -- James H. Stanford, an associate director of Stanford University Hospital, has been named finance director of San Jose Hospitals and Health Center, Inc.

He will assume responsibility for the financial systems of the 728-bed community hospital in downtown San Jose on Dec. 30.

Stanford, 32, came to the Medical School Facilities planning staff in 1967 from General Mills, Inc., in Minneapolis, where he had been assistant to the financial vice president. He was active in the negotiations which led to the University's purchase of the City of Palo Alto's interest in the Hospital, and in July 1968 was one of three top administrators installed when the University assumed management of the Hospital.

He holds A.B. and M.B.A. degrees from Stanford University. He is currently serving as a vice president and director of Big Brothers of America on the Peninsula, and is an active Big Brother. He and his wife and two daughters live in Menlo Park.

STANFORD -- Basic research aimed at eventual prevention of abnormalities of the bones and the other supportive and connective tissues of the body will be conducted in a one-year study at Stanford University Medical Center.

Announcement of a $99,809 research award for the study from the John A. Hartford Foundation was made jointly today (Mon., Dec. 28) by Harry B. George, president of the Foundation, and Dr. John L. Wilson, acting dean of Stanford University School of Medicine.

Principal investigators in the study will be Dr. William van B. Robertson, professor of biochemistry in the Department of Pediatrics, and Dr. Norman Kretchmer, professor of pediatrics and head of the Division of Developmental Biology at Stanford.

Their research group will undertake investigations of the complex biological processes of the mesenchyme, the tissue in the embryo which gives rise to the connective tissues of the body.

Malfunctions of the mesenchyme during fetal development may lay the groundwork for diseases in infancy, childhood or adulthood, such as congenital heart disease, rheumatoid arthritis, Hurler's Syndrome (in which there is an abnormal accumulation of connective tissue constituents, resulting in blindness, and respiratory and heart troubles), osteoporosis (a condition in which the bones become rarefied -- extremely thin), and others.

A concept already appreciated by scientists is that the mesenchyme interacts with the ectodermal (outer) tissue layers during fetal development, regulating the flow of metabolites, nutrients, hormones and drugs. (The ectoderm gives rise to the "functional" cells, such as those of the liver, pancreas, skin and other organs.) By studying the metabolic relationship of the two layers of developing tissue, Dr. Merton R. Bernfield, a pediatrician participating in the research, explains, the group hopes to learn how the mesenchyme affects the complex structure of various organs.

Two constitutents of the mesenchyme, a protein known as collagen, and a group of complex carbohydrates known as muccopolysaccarides,direct the eventual overall shape of organs. Abnormal metabolism in these constituents during the early stages of life may lead to their over-accumulation, deficiency, or distortion later. Collagen is the chief fibrous protein in the body.

The Stanford researchers will direct another portion of their study at examination of the role of ascorbic acid (Vitamin C) in the synthesis and subsequent breakdown of collagen and some of the muccopolysaccarides. "This vitamin occupies a central and unique position in maintaining the integrity of supporting tissues," Dr. Robertson says. "And ascorbic acid deficiency offers the uncommon advantage that it can be turned off and on at will."

A third portion of the research will concern achieving a better understanding of the interactions of steroid hormones and muccopolysaccarides. Steroid drug therapy for many human ailments can cause unfortunate side effects. Knowledge of how these drugs interact with various tissue constituents may be a first step toward creation of steroid drugs with a minimum of bad side effects.

Findings of the Hartford Foundation-sponsored research which have therapeutic value will be applied, whenever possible, to children who are patients at Stanford University Hospital and the Children's Hospital at Stanford. "We hope someday, through this research, to learn how to prevent these disabilities altogether," Dr. Kretchmer said. ###

STANFORD--Stanford University's 100th kidney transplant patient will be spending Christmas at home in San Jose with her parents and three younger sisters.

She is Lola Yutze, a dark-eyed, supremely happy 18-year-old, daughter of Mr. and Mrs. Dennis E. Nelson of San Jose.

Not only is Lola safely ensconced with her family for the holidays, she is jubilant about the fact that the outlook for the new year includes rejoining her class, the 1971 seniors at Branham High School, and graduating on time with them next spring.

Hit with serious illness two years ago (her sophomore year), she was told this past summer by Stanford doctors that a kidney transplant operation was necessary to save her life. In August she entered Stanford University Hospital for the transplant operation, which was performed by a team headed by Drs. Roy B. Cohn and Zoltan J. Lucas. She is Stanford's 100th kidney recipient. The procedure has been done there since 1964.

Lola was dismissed from the hospital in November, and is now back to a pattern of normal activity. She has been out in the stores merrily shopping for Christmas gifts, and, she says, eyeing the variety of teenage fashions. "I look at all the clothes," she says, "I never tire of it."

Above and beyond the enchantment that clothes hold for most girls, there is a practical reason for her big interest: she is back up to a healthy weight and needs to collect an almost entirely new wardrobe. To help the cause, her aunts and uncles and cousins gave her a gift of money for clothes when they came to celebrate her 18th birthday on Dec. 12.

Lola's favorite subject of the four she is taking (through tutors who come to her home) this semester, is art. She thinks interior decorating is a likely choice for a career, something she is actively considering now that all of her interests are picking up again. "Now that I'm feeling really good," she says.

Her family is taking the prospect of her recovery one step at a time. Primarily they are thankful to be reunited with her this holiday. "It's beautiful," says her mother.

STANFORD -- Ever think of the most precious gifts to give or to get this time of year? Oh, you've thought of them all, but money's a little too tight this year?

Well, there is one gift that you probably haven't thought of. And it is certainly one of the most valuable ever--both to give and to get. It is also very cheap to give, although it is enormously valuable to receive. It is also always needed, and at this time of year, more than ever.

It is the gift of blood. Donations decline sharply during holiday time. Consequently, major shortages can result. The blood usually needs to be fresh and on hand at all times, according to Dr. Paul Wolf, medical director of the Stanford University Hospital Blood Bank.

The results of a low blood supply in area hospitals could include postponement of all but the most urgent surgery at a time when accident rates rise, noted Dr. Wolf.

What's more, in the mid-Peninsula area, there is a Community Blood Reserve (CBR). If you are a member, it provides whatever amount of blood needed by you or your family in times of illness, accident or surgery.

For a $2 enrollment fee and an agreement to donate on call no more than one pint of blood once a year to the Stanford University Hospital Blood Bank, with few limitations, all members in a family are covered if they have a need for blood, whether at Stanford or any other hospital.

(This does not pay charges associated with giving a transfusion, or crossmatching tests, which most health insurance plans cover, but works somewhat like a bank account--the blood given is insurance that it will be there for members and their families when it is needed, and at the same time will provide the community with fresh blood at all times.)

For more information about the program, call the Stanford University Hospital, 321-1200, extension 5979. It is sponsored by the Junior League of Palo Alto.

Blood donations can also be made, by appointment, with Stanford Blood Bank, Red Cross in San Jose, Peninsula Blood Bank, Burlingame, and Irwin Memorial Blood Bank in San Francisco.

STANFORD -- A Stanford University psychiatrist says encounter groups can be risky, especially when the leader is aggressive, intrusive, and has a charismatic personality.

Dr. Irvin D. Yalom reports he reached this conclusion after studies showed a nine per cent casualty rate for students taking part in encounter groups. This rate is unusually high by psychiatric standards.

A total of 210 Stanford students were enrolled in encounter groups surveyed by Dr. Yalom. Of the 170 students who finished the study, 16 were termed "casualties" in that they were adversely affected by the group sessions.

Casualties ranged in severity from three students who developed psychoses and severe depression to students who felt their self-esteem had been destroyed.

One student in the test committed suicide, but Dr. Yalom stressed the act could not be blamed on the test encounter group. The patient, who obviously was searching many avenues for help, at the same time had received personal psychiatric attention, and was participating in several other group therapy sessions.

Dr. Yalom, an associate professor of psychiatry, reported on the research Wednesday at a symposium in the Stanford University School of Medicine. Yalom also heads a task force of the American Psychiatric Association studying recent developments in the use of small groups, their dangers and promise.

Seventeen different encounter groups were used for the Stanford study, each led by recognized people in the field. Sessions continued for 30 hours, some on a marathon basis and some on a weekly basis.

Encounter groups have been one of the most rapidly growing movements in the United States, reaching epidemic proportions in the west. These groups attempt to encourage openness,honesty, total self-disclosure among participants. The experience is not labeled "therapy," but the groups strive to increase inner awareness and modify behavior.

In the Stanford study, a cross section of encounter group techniques were used. Included were Gestalt therapy, psychodrama, personal growth, Synanon, and nonverbal.

But the type of leader rather than the ideology, determined how the group functioned, Dr. Yalom found.

Students in groups led by individuals with an aggressive, stimulating approach, with a charismatic personality and sense of mission, were enthusiastic at the immediate conclusion of sessions, Dr. Yalom noted. But the results quickly evaporated. These groups also produced the most casualties.

On the other hand, the long-term followups showed more benefits from encounter groups led by leaders using a low-key or unstructured approach.

Some of these sessions had been so dull that observers fell asleep, but after six months, students felt they benefited, he said.

In the groups with a laissez fair approach, it seems the leaders did not interfere with the development of group feeling. Some were able to enhance and develop it. But the aggressive leaders did not allow it to happen, because they were intruding their own needs on the group, the psychiatrist commented.

Dr. Yalom explained the casualties in the groups were tracked down by questioning the leaders, the students themselves, and by checking with dropouts, and with students who sought psychiatric help.

The leaders were the least sensitive to problems, he said, and often were not aware of the casualties in their group.

Many students enter encounter groups with unrealistic expectations, Dr. Yalom believes. They are lonely, isolated and alienated, and come to the encounter sessions vowing to be different. But it is impossible to get the help they need from a group, and so they become even more discouraged. ### 12/18/70

STANFORD--Dr. Kathryn M. Smith, dean of the University of Colorado School of Nursing, will spend the coming year assisting Stanford University School of Medicine to draft plans for the future of nursing at Stanford.

She has been appointed a visiting professor of nursing at Stanford for a year-long study to develop short- and long-range goals for the School of Nursing.

The study is part of the continuing examination of all activities and programs within the Medical School.

The current nursing program at Stanford offers a basic undergraduate nursing program. Some of the questions to be raised in the study are: Should this program be expanded to include a graduate level? Should there be both graduate and undergraduate programs or is one more appropriate than the other in a university? Which then, and at what length? What are the future roles of nurses and what preparation is required? What special contribution can a university make to the education of nurses?

The Department of Health, Education and Welfare has given Stanford a one-year grant to make this study. The San Francisco Foundation has provided a grant of $25,000 for each of three years to augment and implement the study.

Dean Smith will work in collaboration with Dr. John L. Wilson, acting dean of the School of Medicine, and Miss Grace Ringressy, director of the School of Nursing.

Dr. Smith has been dean of the University of Colorado Nursing School since 1965. She is a 1944 graduate of the University of Minnesota and obtained the Doctor of Education degree from Stanford University in 1964. She served as assistant dean of the University of California School of Nursing in San Francisco 1947-64.

(ADVANCE) FOR PM RELEASE MONDAY, DECEMBER 7, 1970

SAN JUAN, PUERTO RICO –

Evidence that acute leukemia in humans may be evaluated by comparing normal and leukemic regulatory mechanisms of white cells grown in the laboratory was presented Monday, Dec. 7, by a Stanford University medical research team.

The finding is another piece in the puzzle of what mechanisms are involved in the clinical evolution of the fatal disease, which originates in the bone marrow.

The two cell mechanisms used for measurement are called CFC (colony forming capacity) and CSA (colony stimulating activity). Both are essential for the development of normal bone marrow.

In healthy persons CSA stimulates bone marrow cells to grow into colonies of many normal white cells.

But in 15 patients with acute leukemia, studied by the Stanford researchers, bone marrow cells were found to have both impaired CSA and abnormal CFC. In short, the patients had defective bone marrow.

When these patients were treated and temporarily returned to good health, their CSA and CFC became normal, and the marrow began to produce normal cells again, the researchers reported.

The researchers are Dr. Peter L. Greenberg, a postdoctoral fellow in medicine; William Nichols, a medical student; and Dr. Stanley L. Schrier, associate professor and head of the division of hematology at Stanford University School of Medicine. They presented their findings at the meeting of the American Society of Hematology in San Juan, Puerto Rico.

Acute leukemia [the adult type] is a cancer of the bone marrow and lymph nodes where blood cells are manufactured. The disease sends millions of abnormal white cells flooding into the blood stream. It infiltrates and ruins vital organs, and leaves its victims almost defenseless against infection and hemorrhage. The disease is incurable although there are treatments that provide temporary relief.

In their studies, which used newly developed tissue culture techniques, the Stanford investigators have also turned up other significant findings:

–After the sickest leukemic patients entered a drug induced remission, normal marrow cells emerged. It was previously thought normal marrow cells in such patients were completely wiped out. Their presence, according to the scientists, may have implications for treatment.

–The extent of change of CFC and CSA to normal may be useful in defining more precisely the leukemic patient's clinical improvement after treatment.

–Defective CFC and CSA were found in the marrow of preleukemic patients [patients with certain conditions which develop into leukemia over a long period.] Detection of the defective marrow growth and CSA in this system, the Stanford researchers believe, may help in diagnosing leukemia before it is clinically apparent.

However, bone marrow abnormalities due to CFC and CSA deficiency do not fully explain why leukemia in preleukemic patients develops slowly. One speculation is that the body holds the disease in check.

The Stanford researchers have cautioned that a great deal of painstaking observation will be needed before questions raised by their study can be fully answered.

STANFORD -- A new approach to provide aid for stroke patients is underway at Stanford University Hospital and Palo Alto Veterans Administration Hospital.

The programs, which are separate, are both assisted by Area III, California Regional Medical Programs, administered by the Stanford University School of Medicine. The Stanford program's emphasis will be on a coordinated team approach that will have long-range implications for treatment of other disabilities, according to its planners.

Evaluation and aid for all stroke patients at Stanford University Hospital can be put in motion by the simple notation, "Stroke Program," written on the patient's order chart at the request of the attending physician.

Immediately, each patient is evaluated by all the units that will assist in his care. These units involve nurses, doctors, social workers, physical, occupational and speech therapists as well as public health nurses for post-hospital needs. Also important in this effort is consideration of the family's own needs, and its part in the patient's recovery.

This program has been a year in the planning by a University Hospital Stroke Committee, with the help of Regional Medical Programs.

A special stroke coordinator nurse is now on hand to see to it that a comprehensive program for each patient is worked out. Dr. Paul B. Eckman is committee chairman. He is a neurologist at the Palo Alto Medical Clinic and an assistant clinical professor of neurology at Stanford University School of Medicine.

Previously, evaluation and therapy for stroke patients has been variable. A thoroughly planned rehabilitation program has not been automatic. Stroke management seems to have been a continuing problem at the national as well as the local level, although stroke remains one of the top killers and cripplers in the country, according to Dr. Eckman.

The nurse coordinator, Mrs. LaVerne Westerlund, must work with the staff of whatever unit in the hospital that the stroke patient is admitted to, in order to arrange details for each person's care. Such care ranges from teaching the stroke patient how to handle himself to the best of his capacity, to family counseling.

The program is similar to other Regional Medical Programs already underway at Community Hospital of Santa Cruz, and Valley Medical Center in Santa Clara. Other hospitals and colleges in the area are also working out programs to increase training in stroke care, under a new RMP grant.

The Palo Alto Veterans Administration Hospital stroke program will also utilize a team approach but with emphasis on specialized treatment of patients who have predisposing symptoms of stroke, said Dr. William Hofmann, of the VA Neurology Department and associate professor of neurology at Stanford.

The patients, referred by private physicians, will be studied and returned quickly to the referring doctors for follow-up care. The data taken from these patients will also help in a long-range study of strokes.

Non-veterans can now be admitted to certain services of the VA Hospital, under a sharing agreement which became law some time ago. Unfortunately this provision for non-veteran use of VA facilities remains largely unused, Dr. Hofmann noted.

He pointed out the VA Hospital in Palo Alto, with its first-class facilities and Stanford Medical Center staff, operates with some beds empty most of the time and these could be used by the community. Local physicians, however, have not begun to take advantage of this type of an area-wide referral center.

Dr. Hofmann believes that the VA Hospital should and can become a major resource for stroke treatment and training. He points out that the daily cost is less than the cost of similar care elsewhere, and that at least our local county is using the VA Hospital to refer indigent non-veteran patients.

In addition, he states the Palo Alto VA facilities are more elaborate than those in many of the smaller community hospitals in the 11 counties in Central California that are served by the Regional Medical Programs and could well be used as a "back up" resource for special studies. In this way, Hofmann points out, Federal tax dollars which help support the VA hospitals could actually come back directly to the community in the form of services. The whole concept opens up exciting possibilities for over-all quality care, Hofmann is convinced.

In addition, the VA has a training program that will give licensed practical nurses additional skills in the management of stroke patients in nursing homes and extended care facilities.

The VA also hopes to train doctors from neighboring community hospitals in the use of new techniques and equipment in stroke management.

STANFORD -- Dr. Paul H. Jacobs, Stanford Medical Center dermatologist, was presented on December 1 with an award for notable work in clinical dermatology.

Dr. Jacobs, associate professor of clinical dermatology and director of the dermatology clinic, is a recently retired Army Colonel. He was awarded the James Clarke White award, which is given each year to a doctor for outstanding work performed in clinical or research dermatology while employed by the U.S. Government.

The award consists of a plaque and $500 honorarium. It honors Dr. James White, who is regarded as the father of American dermatology. Dr. White, a teacher, writer and clinician, was the first American professor of dermatology when Harvard University established such a chair in 1871.

Dr. Jacobs received the award in Washington, D.C. at a meeting of the Association of Military Surgeons.

Electronic implants may someday replace conventional hearing aids, a Stanford University ear, nose and throat specialist predicts.

The know-how for developing electronic hearing implants is now available, Dr. Richard Goode said, but more animal research is required to evaluate their performance before the devices can be routinely implanted in humans.

So advanced, in fact, is the technology of electronic implants that Stanford University School of Medicine recently sponsored a conference on the subject. Present were doctors, electronic engineers, audiologists and physiologists, an increasingly common association of experts in dealing with many of the problems and approaches of such implants.

These men consider themselves as a kind of avant garde in the study of hearing problems. That present hearing aids are "abominable" was the consesus held by many who attended the Stanford conference.

"We're about where the pacemaker people were 15 years ago," said Rollin Denniston, a Minneapolis engineer who has invented one electronic hearing device. "We're all at about the same place in our research--and now we're after the breakthrough--where people with badly impaired hearing will be able to hear and communicate normally."

Goode pointed out that researchers are now finding out more and more what takes place when sounds are received in the ear and transformed into the neurological impluses that travel to the brain. (The brain then translates these impluses into "recognizable" interpretations--speech, singing, music, etc.)

"The catch" said Dr. Good, "is to use a device that will electronically trick the brain into thinking it has received 'normal' sound waves."

The researchers fall into two categories--those who are attempting to stimulate the hearing nerve (or the inner ear) itself, and a second group whose aim is to stimulate the ear drum, or ear bones into movement. The first group is concerned with the problem of total deafness--where the patient cannot hear; and the second group takes aim at creating a better amplifier for those with impaired hearing.

One such device for hearing improvement is being explored by Dr. Goode and Dr. Theodore Glattke, also of Stanford.

-more-

222--Hearing device

It utilizes, as do conventional hearing aids, a basic concept of electrical engineering, whereby electomagnetic waves are converted into sound waves. In this case however, a magnet is implanted on the ear drum or ear bones. A tiny amplifier with a microphone is worn behind the ear, but instead of an earphone, only a small output coil is used. Amplified electromagnetic waves then radiate from this encased coil to the implanted magnet. As a result, the magnet moves, driving the bones and ear drum, thus producing the sensation of sound.

Total implantation--including the amplifier--is not possible at this time, because of the relatively brief life of batteries, Dr. Goode noted. However, he adds that nuclear power supply will ultimately provide the answer and when that concept is workable, total implantation will be done.

Goode points out that this device has a number of advantages over hearing aides currently in use, including improved fidelity of sound reproduction and also that the customary tight fitting ear mold can be eliminated. This elimination alone offers many advantages: any residual hearing left to the patient can now be utilized since the ear is open. Also important for cosmetic purposes, the wearer's handicap is not as apparent.

Denniston, the engineer, noted that the electronic technique itself was so highly developed that all sounds were coming through with "remarkable" fidelity. He felt that the problem of distortion which has plagued hearing aid users up until now could be considerably improved by the implants.

The remaining problems facing the investigators are centering around such questions as exactly where the implant should be, how long the apparatus will work, how long the device can remain implanted and best methods of getting power through the intact skin to the implant. (The long-term use of wires passing through the skin is of course unsatisfactory because of irritation and infection.)

As of now, there have been very limited experiences with humans to answer these questions, Dr. Goode stressed.

Another Stanford researcher, Dr. F. Blair Simmons, who is working on the delicate and complicated problem of implants for the cochlea, or inner ear, said his work with animals was so far along that "there weren't too many more questions we can ask of the cats."

However, he warned the implant method probably will not work in patients whose hearing nerve is defective. He noted that in some cases, a variety of sounds were received, after electronic stimulation, but speech itself as an "understandable language" remains extremely problematical.

Dr. Goode cautioned that routine application of any electronic hearing implants in humans is at least several years away.

Research at Stanford is being financed through the National Institutes of Health and Veterans Administration grants.

STANFORD -- A new program of comprehensive care for hemophiliacs has been established at the Children's Hospital at Stanford.

The program is under the direction of the Department of Pediatrics of the Stanford University School of Medicine. Children's Hospital, which specializes in the care of children with chronic disorders, is affiliated with the medical school.

A key element in the program is that the boys are taught to administer their own intravenous infusions of cryoprecipitate, the component of blood which contains a specific clotting factor they lack. Once they learn the technique of giving themselves intravenous infusions at home, there are fewer trips to the hospital. Parents and boys are saved countless hours, and medical costs are brought down.

Coordination of all aspects of the boys' health is achieved through consultation among many specialists, an approach which was arrived at "to prevent patients and their families from getting lost in the various subspecialties," says Dr. Jack Lazerson, assistant professor of pediatrics and director of the hemophilia program.

The boys have Classic Hemophilia A, the type of the disorder characterized by an abnormality of a protein in blood known as Factor VIII, which is essential for coagulation. This form of the disorder affects 1 in 10,000 mailes in the United States. (Another form, Hemophilia B, which is not treated with cryoprecipitate, affects 1 in 100,000 males, and there is also a very rare form, Hemophilia C, which affects males and females. In Classic Hemophilia A, the disorder is "carried" by mothers, but appears only in their sons.)

"Before we started making use of a team, parents of these children in the Bay Area had no alternative but to seek help on each separate phase of the problem as it presented itself in the life of the child. They were almost always unprepared for the next difficulty and in general were losing ground in the battle for the boy's well-being," Dr. Lazerson says.

A major difference now is that from the boys' infancy on, parents are fully aware that hemophilia is a complex disorder which can be expected to manifest itself in a number of ways. The parents learn that the separate phases of the problem will be fitted into the comprehensive program and will be closely watched by the cooperating specialists.

Very early in each child's life, the parents come to Children's Hospital at Stanford for a consultation. A social worker meets with them to assist on the financial side of the problem, referring them to local agencies for aid if need be, and telling them about a plan which will enable them to accumulate blood credits.

In the past, Dr. Lazerson explains, the high cost of cryoprecipitate amounted to a major problem for parents, becoming almost prohibitive. Through the comprehensive care program, parents are advised to build up a large credit account by getting regular blood donors far in advance of the time when big quantities of cryoprecipitate may be needed. -more-

Later on, the social worker may be called on to arrange counseling for the boy, the family, or both.

Through private conferences, and in group meetings, parents are thoroughly educated about the disorder--its physiology, how it is affecting their child, and how the genetics of the problem could affect the family in the future.

In addition to pediatricians and pediatric hematologists at the Hospital, the medical team will probably include a physical therapist, nurse, orthopedist and the family's own doctor.

Curiously enough, a process known as "fractionation" paved the way for the downfall of the "fragmentation" of medical care which used to amount to a very unsatisfactory way of life for hemophiliacs and their families.

For them and their doctors, fractionation is a word with a highly positive connotation. It refers to the separation of whole blood into four major components: red cells, platelets, plasma and cryoprecipitate.

The components play separate roles in the body, and are needed only as components by patients with differing needs. For instance, patients with anemia need only the red cells. Patients with platelet disorders need only platelets. Patients with leukemia may at some times need only red cells, and at other times need only platelets. Plasma is provided for patients who have lost blood volume and do not need the cellular components.

Patients with Classic Hemophilia A need the component of normal blood which contains a high concentration of Factor VIII -- cryoprecipitate.

In 1964, a simple method of extracting this component was developed by a physiologist at Stanford, Dr. Judith G. Pool. The technique, which can be carried out at any blood bank without elaborate equipment, involves separating the plasma from whole blood by centrifugation and freezing it within six hours after it is collected, then centrifuging the precipitate formed by the gradual thawing of the plasma.

Last September (1970) the National Institutes of Health licensed cryoprecipitate for commercial production throughout the United States.

Both the technology and the more recent licensure have been important steps in advancing the treatment of hemophilia, and in offering hemophiliacs a much more optimistic view for the future, Dr. Lazerson says.

Blood banks are encouraged to fractionate blood, donors are aware that fractionation means maximal utilization of the blood they donate, and the greater availability of cryoprecipitate has now enabled effective treatment for hemophiliacs, he points out.

Boys who are taking cryoprecipitate on a preventive basis to avoid bleeding episodes (some take it only as symptoms arise) give themselves an infusion at home every 48 hours. They also administer a shot just before sports activity or physical therapy. Internal bleeding, rather than external bleeding, constitutes the biggest threat. The bleeding may occur as a result of a bump, but more often it occurs spontaneously, usually into the joints. Before the use of cryoprecipitate, this bleeding caused the crippling and swelling which so often meant abnormal lives for boys with the bleeding disorder.

Through the comprehensive program, and the use of prophylactic treatment, Dr. Lazerson sees abnormal lives for hemophiliacs becoming more and more a thing of the past: "Already we can see the boys' attendance at school approaching normal and none has been hospitalized in the past year. At the same time, we can see that the more active they are, the better their general health is going to be, so we expect things to improve even more in the near future," he comments.

STANFORD -- Announcement of two new gifts to Stanford University Medical Center came today from Mrs. George E. Boyd, president of the Center's 900-member Auxiliary.

A gift of $10,000 from the Auxiliary will be applied toward the purchase of a pho/gamma scintillation camera system for the Center, and the volunteer group has donated $2,402 to buy a cardiac resuscitation unit for the emergency room of Stanford University Hospital, she said.

Two scintillation camera systems, utilized in diagnostic work in nuclear medicine, are already in use at Stanford. "The addition of a third camera will make it possible for us to greatly extend our diagnostic capabilities," Dr. Joseph P. Kriss, head of the Division of Nuclear Medicine, commented.

In 1968, Dr. Kriss, together with Dr. Elliott Levinthal and William Bonner, members of the Instrumentation Research Laboratory at the School of Medicine, designed and developed accessory equipment to the camera system for radioisotopic angiocardiography, an advanced technique used in diagnosis of heart disease.

During the radioisotopic angiocardiographic procedure, which involves the patient for less than three minutes, the camera displays the movement of injected radioactive material as it flows through the heart and lungs, storing the photographic data on video tape for subsequent replay.

Radioisotopic angiocardiography has proved to be a valuable tool in diagnosis of many kinds of heart ailments, including congenital defects occurring in children, Dr. Kriss commented. He said that with the new camera, specialists at Stanford will be able to take advantage of the added potential the technique offers, both as a tool employed in conjunction with radiologic methods of diagnosis, and for the examination of a larger number of patients.

Mrs. Sharon Rowland, head nurse in the emergency room, said that the addition of a cardiac resuscitation unit means that equipment of this type is now standardized throughout Stanford University Hospital.

The unit incorporates an EKG monitor, heart rate monitor, and an automated alarm which sounds if the patient's heart rate goes above or below normal. A fourth instrument, which completes the unit, is the synchronous defibrillator, a highly refined device which enables an error in the heart's electrical pattern to be corrected at precisely the right point in the pattern, thus restoring the heart to an effective beat.

Heart Transplant #27 ALBERT RUPP

STANFORD -- Albert Rupp, 27th heart transplant patient at Stanford, died Feb. 18 at Stanford University Hospital. He was 36.

He had undergone the transplant operation Jan. 5.

Rupp, whose home was at 5232 Roeder Road, San Jose, is survived by his wife Mary and their four sons.

Of a total of 28 Stanford heart transplant patients, 10 are now alive. Two patients have lived for more than two years.

STANFORD -- New information being discovered about aphasic children may have far-reaching implications for urban ghetto children with learning difficulties, a leading expert on childhood aphasia believes.

Dr. Jon Eisenson said that studies of aphasic children have led him to think that there may be some connection between them and ghetto children who continue to have learning difficulties.

If this can be proven, special learning situations, different from current classrooms, will have to be developed to adequately treat these children.

He cited evidence from recent HEW studies which show that many urban ghetto conditions such as malnutrition and frequent lack of good prenatal and medical care in the delivery of babies create a higher potential for prenatal defects or birth injuries. These defects or injuries may be minimal and so go unnoticed, but they also may be enough to damage the brain's learning capacity.

Eisenson made his comments in an interview Tuesday. He is director of the Scottish Rite Institute for Childhood Aphasia at the Stanford University School of Medicine and a professor of speech and hearing sciences.

"As our research bears out our theories," Eisenson said, "giving us something really tangible to go on, we have found out a very fascinating thing--the left brain or hemisphere is for language listening and therefore for talking. The left brain seems to have a special capacity for processing speech signals as well as for formulation and translation of what is received into sequences of sound--in other words, to hear and make sentences. The left brain also seems to keep or to sort the sounds heard into some kind of order. In contrast, the right brain seems to have control over non-language sounds, such as music and animal noises," he explained.

He reflected: "Everyone can snarl or coo with his right brain in or out of control, but when we calm down, we need the left to explain why we were driven to snarling or cooing. We need our left brain for intellectual and communicative purposes."

"About one-third of the children we've studied at the Aphasia Institute have clear or 'hard' signs of neurological impairment and we are finding out that it is often on the left side of the brain. Another one-third have what we call 'soft' signs of neurological damage--the disturbance is not so marked, and does not show up too clearly on neurological tests."

"Then there is a whole other third group where no neurological impairment at all shows up with the equipment now available. Still, these children have all the learning and speaking difficulties of the more markedly aphasic child. So we are treating them the same way--and getting the same good results." Eisenson believes that the majority of all these children may well have some form of minimal brain damage.

Extrapolating from this evidence is the basis for Eisenson's belief that more ghetto children, born under less than optimal conditions, may also have a higher incidence of such minimal brain damage. "This may be one unconsidered factor in working with these children," he said.

One of the promising techniques in making determination of brain damage is a simple test called 'dichotic listening.' Different speech signals such as digits are presented simultaneously to both listener's ears, and the subject is required to report all that he can recall. The usual finding is for normal right-handed persons to have a statistically greater recall for the digits presented to the right ear than those presented to the left. The same is true for a majority of left-handed persons, indicating that for them, too, the left brain is controlling language function, since we know that the left temporal lobe is processing what the right ear has received. -more-

"The test shows us, then, that brain hemisphere dominance has been established. But aphasic children don't show a differentiation for ear preference on such a test."

"Early indications are that these children are slower than their peers in establishing such dominance. The Institute is now studying the implications of these findings," Eisenson said.

"But we believe the dichotic listening technique--where the questions are aimed directly at the nervous system itself--may be a very good way of getting at the crucial point--is this child able to process speech or not."

The whole aim of diagnosing and treating aphasic children, he said, is to get these children to process the language system faster and more accurately--in other words to get them closer to normal speech.

Eisenson urged that pediatricians and those dealing with all children be alert to the major characteristics of childhood aphasia. He also warns that the reaction of an aphasic child--who hears language as a meaningless jumble of sounds--is often to "tune out": consequently, many behavioral and emotional problems stem from this action. In other words, emotional disturbance only follows the initial fact of neurological weakness or imperfection. In many cases, behavior becomes the "fall guy" while the initial difficulty remains undiagnosed and untreated.

He stressed the importance of early treatment, before emotional defenses against the frustrations of not understanding speech could be set up.

"How many times I have heard a distraught family tell me that the child clearly hears the doorbell or the cat's meow, but isn't paying any attention to what we say, and that consequently, they cannot manage the child at all."

"Yet, this left brain disturbance, which seems to have control over language, explains this inconsistency. The child really can't understand clearly what his mother or teacher is saying. However, his right hemisphere permits him to understand the environmental noises that his family reports he responds to."

Asked about differences between normal and aphasic children, Eisenson noted that among the differences, the aphasic child physically is not able to store and recall language sounds as well as normal children, and also he lacks some ability to generalize about language, while other children use this generalizing ability intuitively in helping them learn to speak.

He also cannot pick up clearly or distinguish word patterns and he is slow to combine words into even primitive sentences. Then, he continues on this same primitive sentence level far longer than do other children his age.

While there is also sometimes an auditory impairment, tests show that the amount of hearing loss is not sufficient to explain the severity of the language difficulty, Eisenson noted.

How do we know, then, they are not mentally retarded, Eisenson was asked. He noted that mentally retarded children actually have a greater language facility than aphasic children. The difference comes in the mentally retarded's difficulty in making abstractions or handling complexity of thought and they also have difficulty in non-language tests, while the aphasic children generally do considerably better on them. While childhood aphasia was medically recognized 20 years ago, these children continue to be badly misdiagnosed by psychiatrists as well as pediatricians, Eisenson said.

It is in this regard, he continued, that there may be many more aphasic-like children in our schools than has been realized. And because of the high risk for prenatal or birth defects to children born into ghetto conditions, these children who have major learning difficulties deserve specialized attention, especially in the nursery school and primary grades, Eisenson said. ###Mailed Feb. 23,1971.

Heart Transplant #29 Harry Knudsen

STANFORD -- Harry Knudsen is in satisfactory condition today at Stanford University Hospital after a heart transplant operation February 22.

Knudsen, 47, of Pleasant Hill, California, retired because of his failing heart, was previously in charge of the ski department in a large sporting goods store in Berkeley.

He wife, Inez, is a registered nurse. They have a son Jim, 22.

The donor was Jack Nye, 26, of San Jose who died from a motorcycle accident late Saturday, February 20. His kidneys were also used in two unrelated kidney transplant operations February 22. Nye is survived by his mother and stepfather, Mr. and Mrs. Donald Monahan of San Jose.

Knudsen's transplant operation was performed by a team headed by Dr. Norman E. Shumway.

He is the 29th heart recipient in operations performed at Stanford. Of these patients, 11 are surviving, including Mr. Knudsen.

STANFORD -- Meet Sean.

He's 15, he's bright, athletic and he's strong on ecology.

The other week, he went with fellow Ecology Club members from John Muir School in San Jose to help clean up the beach from the oil spill.

The only catch is that Sean couldn't have gone if he hadn't had eight units of cryoprecipitate (cryo), the blood component containing the antihemophiliac factor, the night before.

Sean is a hemophiliac and without constant infusions of cryo, he might be an invalid, unable to walk, much less go to school or help to clean up the beaches. And Sean is quick to understand and appreciate that his own tie to his fellow man is an illustration of an exceptionally close human ecology link.

"It is a contribution to the life and health of another for which there can be no substitute," Dr. Paul Wolf, medical director of the Stanford Blood Bank, said.

Yet every week many hundreds of patients in Northern California need blood, but only five per cent of the people in the area who can give blood actually do, Dr. Wolf added.

In Sean's own case, donations in his name to the Stanford University Hospital Blood Bank will literally fill a double bill. The Blood Bank will have the blood on hand for Sean, or whoever needs it, and a major hospital bill will be paid at the same time.

Sean has used thousands of dollars in blood, but if there are 42 new whole blood donations in his name, one particular hospital debt of $1051 will be wiped out. In addition, the other blood components will be used for patients with different needs. (Whole blood can now be separated into four parts -- platelets, red cells, plasma and cryoprecipitate, all of which are needed and go for different patients, Dr. Wolf explained.)

-more-

Sean's $1051 bill ran up when he was brought to the Stanford Hospital's Emergency Room on many previous occasions and when he was hospitalized for some months in 1970.

The outlook is brighter for Sean now because he is under a new preventive program underway at Children's Hospital at Stanford. The program is under the direction of the department of pediatrics at the Stanford University School of Medicine, and is headed by Dr. Jack Lazerson. At Children's Hospital, which is affiliated with the medical school, Sean is taught how to infuse the cryo at home, three times weekly as a preventive measure. He can also treat himself if he has been hurt in any way. All injuries or bruises will always go very hard on Sean; internal bleeding starts immediately and tissues are damaged enough to cripple him, if he does not receive a prompt cryo infusion. Formerly, Sean had to receive blood on an emergency basis in the hospital.

"Being on the new preventive program has made all the difference in our lives", Sean's mother commented.

"But Blood Banks never have enough blood", Dr. Wolf warned. An official from the Irwin Blood Bank in San Francisco noted recently, in the same tone, "People must start accepting the responsibility for making blood donations in advance of need and replacing blood used with blood itself."

Dr. Wolf pointed out that for ecology-minded Sean and many others, they need what is actually readily available, but cannot be bought or made except by another human being -- the continuing, prized gift of blood. "It becomes life itself to those who need it," Dr. Wolf stressed.

The Stanford University Blood Bank urges people to call for appointments, however, because it is not currently equipped to handle more than two donors at one time.

The number is 321-1200, extension 6111.

PALO ALTO--The Stanford University Medical Center Auxiliary today (Wed., Feb. 24) elected Mrs. R. Gordon Gould of Stanford its 1971 president.

Mrs. Gould will succeed Mrs. George E. Boyd of Los Altos Hills, who has served as the 900-member organization's top officer for the past two years, on April 1.

During Mrs. Boyd's two terms Mrs. Gould has held the office of first vice-president, and the appointed job of chairman of volunteer services.

The wife of a specialist in metabolic diseases and endocrinology at the School of Medicine (Dr. Gould is associate professor of biochemistry in the Department of Medicine), and mother of a son and daughter both pursuing doctoral degrees, Mrs. Gould has been a volunteer at the Medical Center since 1960. From 1963 to 1966 she was staffing chairman for the hospital gift shop. Through this enterprise, and the baby photo service at the Hospital, the Auxiliary raises the money it donates to the Medical Center.

She was elected at the organization's annual meeting, held at Ming's Restaurant.

Other new officers are: Mrs. John Bohler of Atherton, first vice-president; Mrs. Robert Bush of Palo Alto, second vice-president; Mrs. Robert Anderson of Los Altos, corresponding secretary; Mrs. Charles Frost of Palo Alto, recording secretary; Mrs. Harold Hjelm of Menlo Park, treasurer; and Mrs. Arthur Gleim of Los Altos Hills, assistant treasurer.

Newly elected to the Board of Directors are: Mrs. Oliver Whitby of Los Altos Hills, who is Auxiliary membership chairman; Mrs. Frost and Mrs. Gleim.

Mrs. Glenn Hitchcock of Menlo Park, Miss Anne Ramsay of Palo Alto and Mrs. Daniel Williams of Palo Alto were re-elected to the Board.

New members of the nominating committee are: Mrs. Hitchcock, Mrs. Williams, Mrs. Bush, Mrs. Reece Dorr of Menlo Park and Mrs. John Dusterberry of Palo Alto.

The volunteer organization, under various names, has been continuous since 1929, when it was founded as the Palo Alto Hospital Auxiliary.

STANFORD -- The National Science Foundation has awarded Stanford University a $375,000 grant to design and construct a hospital prototype of a pion facility for cancer treatment.

The prototype will be built at Stanford's High-Energy Physics Laboratory and preliminary tests of the system will be undertaken there. It will be installed in a special facility in the Stanford University Hospital, if initial experiments prove that a superconducting linear electron accelerator can provide a beam of negative pions of sufficient intensity to be practical for cancer therapy.

Pions or pi mesons are negatively charged subatomic particles hitherto unused in radiation treatment of human cancer. This is because accelerators capable of generating pi mesons adequate for cancer therapy have thus far been available only from extremely large and expensive machines. Such a machine is the $56 million, half-a-mile linear proton accelerator in Los Alamos, New Mexico.

But Stanford physicists H. Alan Schwettman and William M. Fairbank believe that through advances in the field of low temperature physics they can now construct a smaller, 50-foot accelerator. This machine would generate streams of pi mesons for cancer therapy for about one-tenth the cost of the large machines.

Moreover, the physicists feel they can build a pion channel or collection system that would be 100 times more efficient than that of Los Alamos. A pion channel is a device with powerful magnets for capturing the pi mesons as they are generated by the accelerator for delivery to the patient. Accelerator energies of about 500 million electron volts are needed to produce 100-million-volt mesons for cancer therapy.

The project is under the direction of Dr. Schwettman and Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology at the School of Medicine.

The investigators said if initial experiments prove that a pion facility is feasible, then for a construction cost of approximately $5 million, one might hope to treat 1,000 patients a year. The proposed concept would include the accelerator itself, four pion channels for treatment, and a variety of support services in an underground building attached to the hospital.

"Fifty such facilities across the country could have a major impact in the treatment of cancer, and over a period of 10 years the construction cost of these per patient would be small," the researchers said.

To test the practicality of pi meson treatment, the researchers will use a new superconducting linear accelerator just built on the Stanford campus strictly for basic physics research under the auspices of the Office of Naval Research and the National Science Foundation.

This 500-foot, powerful atom smasher, maintained in a supercooled state in a bath of liquid helium, is able to generate negative pi mesons by interaction of its electron beam with an appropriate target.

-more-

The medical-physics team will construct one pion channel as a hospital prototype that will be operated in connection with this linear accelerator. The pion channel will collect by means of magnets the negative pi mesons as they emanate from the target and deliver them by computer-controlled adjustment to the desired area in the body.

With this system and under simulated hospital conditions, the scientists will make the necessary studies to develop standards for the most effective use of pi mesons in cancer patients.

If all goes well, the researchers anticipate planning and building a pi meson facility in the Stanford University Hospital for the purpose of controlled clinical trials. Such construction, however, is at least five years away.

The theoretical existence of the negative pi meson was predicted by physicists 35 years ago, and its physical demonstration took place 10 years later. The reason, however, these subatomic particles interested radiotherapists is because they produce a microscopic atomic detonation within the tumor area when they collide with atoms of oxygen, carbon, or nitrogen of target cancer cells. But while they deposit great destructive energy in the tumor mass, pi mesons do not harm healthy tissue on the way in.

For this reason, Dr. Kaplan and his colleagues believe the powerful pi mesons may well prove to be the most ideal source of radiotherapy of human cancer.

Cures are governed by the injury to normal tissue, and pi mesons promise less injury than any other particle, he noted.

Increased accuracy through use of pi mesons would extend treatment to other elusive and rapidly spreading forms of cancer which cannot be treated with conventional accelerators, he said.

It is estimated that of the half a million cancers occurring annually in the United States, 50 per cent receive radiation therapy for cure or alleviation of pain. Improvements in radiotherapy techniques in the past 20 years have already resulted in dramatic increase in survival rates, notably among patients suffering from Hodgkin's disease.

Other scientists associated with the joint physics-radiology project are Dr. Malcolm A. Bagshaw, professor of radiology; Dr. Douglas P. Boyd, research associate at High-Energy Physics Laboratory; Dr. Robert F. Kallman, and Dr. Clarence J. Karzmark, both associate professors of radiology.

In the mid-1950's, a similar cooperation between Stanford's radiology and physics groups resulted in the development of the first electron beam linear accelerator for cancer therapy in the Western hemisphere.

STANFORD -- Stanford University Hospital will offer nurses a six-month course in operating room techniques beginning June 7.

Applications are currently being accepted, and should be in by May 1, according to Mrs. Ludmila Davis, R.N., director of the operating room at the hospital.

Applicants must be graduates of accredited schools of nursing, and be currently registered with the California State Board of Nurse Examiners. They should also be in good health and have a definite interest in surgery, Mrs. Davis said.

One of the program's objectives is to develop a clear understanding of surgical procedures.

A moderate monthly stipend will be paid during the six-month (full-time) course.

Interested nurses should telephone the operating room at 321-1200, Extension 5620.

STANFORD -- A $1,000 grant for research in eye disease has been awarded to Stanford University School of Medicine by the Northern California Society for the Prevention of Blindness, Inc.

The grant will enable Dr. Gerald L. Portney, assistant professor and director of the Stanford Glaucoma Service, to investigate the effect of various drugs on glaucoma. Glaucoma is an eye disease that is characterized by greater than normal pressure within the eyeball, and interferes with the field of vision.

The National Society for the Prevention of Blindness, founded in 1908, is a voluntary agency engaged in the prevention of blindess through community service, public and professional education, and research.

STANFORD -- Dr. Thomas A. Stamey, professor and head of the Division of Urology at Stanford University, has been appointed member of the scientific advisory board of the National Kidney Foundation.

Dr. Stamey is an authority on kidney physiology, urinary tract infections, and hypertension. He is also author of a book about the methods of studying kidney conditions in man which lead to high blood pressure.

STANFORD -- Dr. John J. Miller, III, assistant professor of pediatrics, has received a $30,000 grant to study the relationship of drugs to the lupus syndrome. The grant has been awarded by the Pharmaceutical Manufacturers Association Foundation, Inc. Lupus is a serious inflammatory disorder affecting many organ systems of the body.

STANFORD -- Two scientists from the Stanford University School of Medicine have received research grants totalling $101,528 from the American Cancer Society.

A two-year grant of $64,028 will go to Dr. Thomas E. Schroeder, assistant professor of anatomy, for work in clarifying the mechanism of cell division as an aid to better understanding uncontrollable growth in cancer cells.

Dr. Robert T. Schimke, professor and chairman of the Department of Pharmacology, received a $37,500 grant for studies in protein control and the formation and utilization of enzyme animal tissues.

STANFORD -- Student interest in "relevance" is being put to test and to practical use in helping emotionally disturbed children in Palo Alto.

The students are volunteering at Peninsula Children's Hospital, a day care facility for disturbed children, whose staff members say they are glad for all the help they can get.

The students are from Stanford University and Medical School, Foothill and other area colleges.

"It is a trip inward, coming to deal with your own emotional reactions in the face of major difficulties in establishing any kind of a relationship with these children."

"A sometimes overwhelming but moving experience to find out how human we all are--whether sane or disturbed--to learn that none of us is so separate."

"The work is demanding but it excites intellectual interest--the students can read the theories later with more understanding."

This is a sampling of the diverse--although by no means contradictory--depth of impression coming from the director and students who are working at the Peninsula Children's Center.

The director is Dr. E. David Burk, assistant professor of psychiatry at the Stanford University School of Medicine.

Burk firmly believes that to be successful and to maintain an interest in the mental health programs (for which there is such a continuing and urgent need for personnel) the volunteer needs to be an essential part of the overall treatment. Therefore, volunteers at PCC learn first hand how these children are treated by working with the children themselves. Their main task is to help the children relate more to the outside world.

Starting next quarter, both med students and undergraduates can also get academic credit for their efforts. Three courses will be offered out of the Department of Psychiatry and will use the PCC as a practical learning laboratory, under Dr. Burk's close direction.

As an additional benefit, the students see at first hand how the various specialists at the Center work with the children--the same children that they themselves may have been working with a short time before. The field is wide open for observation, comparison and learning.

"You get a chance to see how different therapists and diverse styles can still be effective. Then, you learn how to better express your own intuitive response to these children," noted Jim Corby, a fourth year medical student, who plans to go into psychiatry.

The children at the Center are severely schizophrenic or autistic and probably could not function except in a state hospital, if it were not for the Center with its dedicated professional staff and volunteers.

Many of the children have a very high IQ, but it is short circuited or so locked inside of them that very little use can be made of it. "It is as though these children have small islands of normality, or even of genius, and right now, the best we can do is enlarge these islands, if we can, in their relation to the outside world," noted Dr. Burk. -more-

It is in this area that the volunteers are particularly effective. "Their spontaneity, their own outlook which is often fresh and imaginative, and their willingness to give of themselves are wonderful assets," Dr. Burk said.

One characteristic of these disturbed children is that they often treat other human beings as objects, acting unaware of their very existence. Therefore, it is often extraordinarily difficult to relate to them. In addition, their attention span is short, although sometimes their perception of people and events can be correspondingly swift and acute.

All the student agreed that "incredibly" personal relations between themselves and the children developed, but the rewards were minimal if they were looking for major improvement in the children's behavior. But the improvements noted, while often minute, were very real and exciting, both Dr. Burk and the students agreed.

For instance, a child came darting over to a visitor, the doctor and a volunteer. The child swiftly touched everyone and ran off. "Yes," said Dr. Burk to the child, "It's fine to touch, not to hit." He added that the child was just learning to make this distinction. "He used to run up and pound on anybody he saw," Burk said. Both therapy with the professional staff and the patience and interest of volunteers in working with this child have played a major part in helping him, he continued.

The students put it this way: "You get no reinforcement of your own emotions as you do with normal kids, but all the relations with these children are moving and interesting. It hurts, though, when you think you can reach them and then you see that nothing has really changed in their attitudes. But they're still very human children. Endlessly, I learn about life from them and my own responses to them."

"It is depressing at first, but you begin to see that with their amazing alertness and with your own input you can help them. It is a tremendous challenge to try and set up situations that are more advantageous both to yourself and to the children."

A visitor at the Center could see first hand the students' own lack of fear, sturdiness and spontaneous--but controlled--involvement. One held a screaming child, unanxiously paying no attention to his writhing; another watched a husky older boy furiously kicking a wall, intervening, it seemed at just the right moment with a cool, "Hey, cut it out now. Come and help us fix this kite," which the boy promptly did; another talked to a child about the clouds, the sky and the astronauts in an earnest discussion, visibly interested in what the child had to say, but including at the same time another child who kept repeating, "I don't want to listen to what you are saying," but who was listening nevertheless. (Volunteers have learned that it is a common characteristic of these children to give two simultaneous but opposite messages, such as yes/no or want/don't want.)

"These children are part of life--they cannot and should not be walled off. They are everyone's concern," Jim observed.

And Errol Dendy, another fourth year medical student said, "These children's fears, pleasures and other feelings are often a highly exaggerated version of what we all feel at times. But it takes a great effort to work with them."

Errol continued, "The real story should be about the staff and the volunteers who work with them full time. We students go back to our own studies and other interests often with a sense of humility and sometimes, relief. The learning for us is fantastic."

And from Jon Sterngold, another med student, "You get as much as you are able to put into it, but sometimes what we learn from the children is more than we can give to them."

Heart Transplant #30

STANFORD -- Frank J. Losole, a 36-year-old former mechanic, is reported in satisfactory condition today at Stanford University Medical Center after undergoing a heart transplant operation Monday evening (MAR 22).

Losole is from Southgate, California, a suburb of Los Angeles.

He is the 30th patient in the series of heart transplant operations performed at Stanford by Dr. Norman Shumway and his team beginning in January, 1968. There are 12 (twelve) survivors.

STANFORD -- A hopeful new rehabilitation program for heart patients is underway at the Palo Alto YMCA. It consists of an exercise plan under a doctor's supervision.

The program is open only to those who have a history of coronary artery disease and who are referred by their doctors.

Several recent studies have shown that consistent endurance exercise has lowered the death rate of patients with heart disease. One of the aims of the program, says Dr. Gary Fry, the cardiologist in charge, is to show that longer lives do result for such patients. Dr. Fry is on the staffs of the Palo Alto Medical Clinic and the Stanford University Hospital.

Also, he noted, it is well known, and documented by psychological testing that there is frequently an element of depression among coronary patients. "But other tests show clearly that such patients on a conditioning program have less depression. We are finding out that there is a correlation between exercise and a more optimistic outlook, which in turn may also have some direct beneficial effect on the patient's general health."

When a patient starts this program, he is given an electrocardiogram while working out on a stationary bike. From the reading obtained of the heart's activity, an exercise "prescription" is made up, showing just how much each patient can and cannot do. New tests are given at six months and at the end of a year.

Patients who have suffered a heart attack can also be admitted into the program, but only after three months have elapsed from onset of the attack.

These individual programs are watched over by Rob Pierson, physical director at the YMCA and are also supervised by Dr. Fry who exercises along with the patients. He says that he is glad for consistent workouts himself.

The patients meet as a class for three or four sessions a week, from 5 to 6 p.m. The expectation is that they should stay in the class for at least a year. "Sporadic and unsupervised exercise may actually be detrimental to patients. By having them with us a year or more, we can keep a closely supervised, graded control over them," Dr. Fry explained.

The hour program has a warm-up period of calisthenics (which loosen the body, eliminating the hazards stemming from tight joints and muscles); 35 to 40 minutes of walking and jogging (all done inside the gym), based on exactly how much the patient can be allowed; and 5 to 10 minutes of a cooling down period of light exercise. "This last is very important because it lowers the blood pressure in a gradual way. Conversely, it can be very harmful to simply stop peak exercise activity without any time to taper off," says Dr. Fry.

Funds for the patients' initial testing are provided by Area III, Regional Medical Programs, (RMP) which is active in promoting activity in heart, cancer and stroke treatment and prevention. The Stanford Medical Center administers RMP in 11 counties in central California.

The class fee itself is paid for by the patients: $100 for 26 weeks, $200 for the recommended one-year program. The classes are open for new patients at any time.

While patients are accepted only on their doctor's referral, more information can be sent to them or their doctor by calling the Cardiac Rehabilitation Program at the Palo Alto Medical Clinic, 321-4121.

STANFORD -- Proposed creation of a new federal agency to fight cancer would be a mistake, Dr. Joshua Lederberg of Stanford University said Tuesday (MAR. 16, 1971).

The Nobel Laureate in genetics said that "all health research should be knit together within a single agency, specifically an augmented and strengthened National Institutes of Health."

Lederberg said that when a separate agency to lead a national crusade against cancer was proposed, he publicly favored it. This was because he thought a new organization might be a way to avoid traditional bureaucratic restraints and inconsistency that have hampered health research in the past several years.

Since then, however, developments have led him to conclude that a separate agency for cancer is not the best choice.

Among the new developments Lederberg listed:

. President Nixon's new public commitment to health research in general, and cancer in particular.

. evidence of a new balance, consistency and efficiency in administration of the Department of Health, Education and Welfare under Secretary Elliot Richardson's leadership.

. statements by President Nixon's science adviser Edward David on the integrity of basic scientific work in the health field, and the disadvantages of extracting cancer work from the NIH.

Lederberg expressed his views in a letter to the subcommittee on health of the Senate's Committee on Labor and Public Welfare. The subcommittee is conducting public hearings in Washington on a bill which would remove the National Cancer Institute from the NIH and move it to an authority that would report directly to the President.

Proponents of the bill claim that a national crusade against cancer would be seriously handicapped by the present administrative set-up because of delays in decision-making, overlapping functions, and most important, competition for funds.

The separation of cancer research from the rest of biomedical research, now under the umbrella of the National Institutes of Health, is regarded a serious managerial error by the Nixon administration.

"The country would be better served by reinvigorating the NIH as an integral unit than by inventing new streamlined procedures for the benefit of an excised and transplanted cancer authority," Lederberg wrote.

Earlier in an article in the Washington Post, Lederberg said that any authority which is established to pursue a "cure for cancer" as a national goal, must fix a consistency of purpose.

"Health research policy has been flawed for the past several years because of frequent changes in outlook on what constitutes a federal responsibility in this area," he said.

- more -

Lederberg also called for broadening the base for research on human cancer, and cautioned that a crusade against cancer is an oversimplification, with a potential for backfiring if unachievable hopes are aroused.

"I believe that 'Cure Cancer' is a misleading slogan," he wrote, "but only because cancer prevention is a far more promising approach than the cure of the disease once established. Prevention also offers the most incisive channels for exploiting basic molecular and cell biology."

Lederberg admitted that prevention is not as glamorous as cure by surgery or radiation, and a citizen who may balk at another dollar's outlay for preventive public health will spend a fortune to root out his own cancer after the fact.

"Human nature, however, still does not exclude the eventual use of rational intelligence to help decide among policy alternatives," the Stanford geneticist said.

Lederberg said earlier diagnosis of certain cancers, and new treatments in surgery, radiotherapy, and drugs have reduced the inevitability of dying from cancer, once detected.

"Nevertheless, the aggregate rate of death from cancer is still rising, mainly because of lung cancer cases attributable to cigarette smoking and air pollution," he said.

Lederberg stressed that cancer treatment, now available in the nation's best-staffed centers, should be available to more people, but he added: "We simply do not have the basic knowledge to do more than gain time with many cancers after they have reached a certain state of development."

At present about one person in six dies of cancer, Lederberg said, and the best available and costly treatments probably could not improve that figure below one in ten.

"This would be a notable achievement," he said, "but it would buy fewer lives per dollar spent than many other unmet opportunities. For really important progress we must acquire and use new knowledge for the prevention of cancer."

The greatest promise for eradication of cancer according to the Stanford geneticist, comes from the great leaps in basic biological knowledge of the last decade, many in studies of DNA, the genetic material in viruses.

"These have so far given only a few answers centrally connected with human cancer," Dr. Lederberg commented, "but we are now able to formulate sensible questions about the nature of the cancer cell and the origin of its deadly differences from the normal."

Lederberg said that changes in cancer incidence in different eras and in different occupations and geographical areas, give the strongest hopes for preventive measures.

"They speak to the importance of specific environmental factors rather than letting us acquiese ignorantly to cancer as an inevitable lighting bolt," he said.

Many forms of cancer, the geneticist wrote, will be found to be related to known environmental hazards--chemicals to which people are exposed at work and home, and chemicals used as food additives or drugs. This area, more than any other, needs only money to give prompt returns in reducing environmental cancers.

Lederberg said he expects important advances in control of cancer to come from the field of immunology. Recent work has thrown light on the role of the immune system hitherto thought of mainly in connection with infectious diseases like smallpox, polio, and diphtheria.

He said immunologists now believe that many incipient cancers are normally eliminated in the healthy body. However, a weakening of the immune system may allow a cancer seed to escape this surveillance and grow.

When the immune factor in cancer is clarified, scientists hope to be able to develop specific vaccines.

Lederberg's own view, however, is that scientists are more likely to learn how to protect the overall health of the immune system as a bulwark against cancer.

STANFORD--A precision tool, expected to have a major impact on the care of children with birth defects and on genetic counseling for their families, has been installed in the clinical laboratory of the Stanford University Hospital.

The new tool--an amino acid analyzer--can give doctors an exact quantitative picture on paper of the levels of amino acids contained in body fluids.

Amino acids are the substances used in the formation of proteins, the building blocks of body tissues. Abnormal elevations of amino acids in body fluids are associated with genetically-directed errors in metabolism, the processes by which foodstuffs are broken down and tissues are built up.

When these errors cause interruptions in metabolic processes, amino acids are not being utilized correctly in protein formation. The result is that they increase in blood and "spill" into urine.

"In one run of a very small sample, we can test for the absence or presence, and the level, of 40 different amino acids," explains Dr. Klara Efron, who is in charge of the new amino acid program at the hospital laboratory.

A pediatrician who has been researching amino acid metabolism for the past 10 years at Stanford, Dr. Efron collaborated with Sondell Scientific Instruments of Palo Alto in the adaptation of the analyzer to clinical use.

She said, "The instrument will help the doctor to see where the defect lies."

Defects in body chemistry cause mental retardation, convulsions and eczema in phenylketonurea (PKU); cirrhosis of the liver, kidney damage, and loss of intellect in Wilson's Disease; or numerous muscular difficulties and mental retardation in the condition known as Maple Syrup Urine Disease. There are many other defects associated with abnormal amino acid metabolism.

Some birth defects are treatable (controllable, not curable) with drugs or diet; for others no treatment is presently known. PKU, for example, is controllable with a special diet. A drug known as D-penicillamine can slow down the course of Wilson's Disease.

As yet, little can be done for babies affected by Hurler's Syndrome (bone, liver and spleen damage, blindness, and mental retardation). But if the condition is diagnosed early in the life of a child, the parents can be advised to prevent the birth of another defective baby.

Other advantageous features of the new analyzer are its relative speed--one run takes five and a half hours compared with twice as long in other systems, and its ability to test for all the amino acids in one run, which makes for less chance of error.

Dr. Efron explains that no chemicals are added to the sample. It is prepared for analysis by a process known as ultrafiltration, which produces a solution free of any substances which would interfere with the test.

Currently, Dr. Efron is establishing normal ranges of amino acid content for adults and for children of different ages.

Target date for putting the analyzer into general use is May. 3-11-71

STANFORD--Dr. Morris Fishbein, noted author, lecturer, and columnist for Medical World News, will speak at Stanford University School of Medicine Wednesday afternoon (March 17) on "Today and Tomorrow in Medicine."

His talk, which is sponsored by the Department of Dermatology, will be given at 4:30 p.m. in Room M-106 of the Medical School.

Perhaps best known as editor of the Modern Home Medical Adviser, he is the editor of 15 other books and author of 25. He served as assistant editor of the Journal of the American Medical Association from 1913 to 1924, and as its editor from 1924 to 1950.

A resident of Chicago, Dr. Fishbein is a board member of several medical and civic groups in that city, including the Environmental Control Appeal Board, which he was appointed to last year.

He received the M.D. from Rush Medical College in 1912, and is an emeritus professor at the University of Chicago and the University of Illinois College of Medicine.

STANFORD--New positions for Courtney Jones and Frank Vitale, both long associated with Stanford University Medical Center, have just been announced.

Courtney Jones, former deputy director of Stanford University Hospital, has been named director of fiscal affairs for Stanford University Medical Center, and Vitale has been named deputy director of the Hospital. The new appointments were announced today by Dr. John L. Wilson, acting dean and executive officer of the Medical Center, and Dr. Thomas A. Gonda, director of the Hospital.

Jones, 35, becomes responsible for all financial affairs of the Medical Center, including budgeting and long-term financial planning. He will recommend fiscal policy and will correlate this policy with that of the University. His appointment is part of the continuing steps to unify the structure of the Medical Center, Dr. Gonda noted.

Closely identified with the University and the Hospital since receiving his MBA in Business Administration from Stanford in 1962, Jones was with the Controller's Office at Stanford for five years. He came to the Medical Center in 1967 to a newly established post, director of business and finance, but was soon transferred to the Hospital as deputy director, to assist in the reorganization of the Hospital administration.

Currently, in view of the complexity and scope of fiscal operations which involve the Medical School, the Hospital, Clinics and the University itself, the post of director of fiscal affairs has been established.

His professional affiliations include the financial management committee of the California Hospital Association. Jones is also an officer and member of the Community Blood Reserve. He and his wife and their three children reside in Menlo Park.

Frank Vitale, former associate director of the Hospital, becomes deputy director, reporting directly to Dr. Thomas A. Gonda, Hospital chief.

Vitale is a specialist in medical facilities engineering and management. As associate director he has been in charge of the Medical Center's services, which have included engineering and maintenance, fire and safety and industrial engineering. He has been at the Stanford University Hospital since 1961, when he was appointed plant engineer, soon rising to assistant, associate, and now, deputy director.

He is also an advisor to a national hospital consulting group, founded by doctors, which has built over 450 hospitals across the country.

Vitale, 41, was graduated in 1949 from the U.S. Merchant Marine Academy with a B.S. degree in engineering.

He is married, with two children and resides in Menlo Park.

His professional affiliations include membership in the American Hospital Association, the American College of Hospital Administrators and the National Association of Power Engineers.

Heart Transplant #28
1/11/71

STANFORD -- Mrs. Ianza Kingsley is in satisfactory condition at Stanford University Hospital after a heart transplant operation Monday morning, January 11.

Mrs. Kingsley, 48, of Sacramento, California, has been disabled since a massive heart attack in September, 1970. Up until the day before her heart attack, she had worked as a stitcher operator at California Pine Box, a Sacramento factory.

She has three grown children: Carolyn, Loretta and David, and one grandson, Michael.

Mrs. Kingsley becomes the 28th heart transplant recipient in operations performed at Stanford. She is the third woman to undergo such an operation here.

The donor is anonymous.

The 27th patient, Albert Rupp, who received a new heart on January 5, is also reported to be in satisfactory condition.

Both operations were performed by a team headed by Dr. Norman E. Shumway.

STANFORD -- Stanford University Hospital now assigns a personal representative to each patient who is admitted.

Joining the cast of uniformed personnel at the hospital, the patient representatives are distinctive in stylish green and white outfits which can be worn as a suit, skirt and blouse, or jacket dress.

Their role is to individually provide the patient and his family with continuity on all financial matters related to the hospital stay. Before the new system was put into effect, patients or family members had to contact several people regarding financial information and arrangements.

Now all the business details of admitting, credit checking, insurance coverage, deposits, eligibility and certifications for state and federal health insurance, and transferring to another hospital or convalescent home are handled centrally.

A thoroughgoing training program at the hospital last year prepared the nine patient representatives for the new job. In addition to instruction in the range of business procedures, their course included talks by members of the hsopital's social service, nursing, and (post-hospital) placement staffs.

STANFORD -- An old portrait belonging to the Lane Medical Library of Stanford University has been restored to excellent condition, but a puzzle has shown up in the process.

University archivist Ralph Hansen has told the Library that the distinguished looking nineteenth century gentleman is not Timothy Hopkins, after all. Just who he really is, is what the Library wants to find out, and they will be grateful for any clues which could help in the identification process.

Miss Clara Manson, chief medical librarian, found the painting over 20 years ago in the attic of the old Lane Medical Library Building in San Francisco.

"I was told then," she says, "and it never occurred to me to doubt, that it was a portrait of Timothy Hopkins, friend of the Leland Stanford family and later a benefactor to Lane Library.

"After it was sent to the art restoration department, the archivist told us that Hopkins was only 25 years of age in 1880, the year the portrait was done. This gentleman is obviously quite a bit older than 25."

The artist was Frank M. Pebbles, a well known painter in the United States during that era.

"We are seeking help from anyone who can put us on the right track toward the correct identification," Miss Manson said.

Telephone calls regarding the painting may be directed to Miss Manson at Lane Library, 321-1200, Extension 5111; or Mrs. Charlene Levering at the Art Restoration Department, 321-1200, Extension 5225.

Editors: Photos available upon request if not included with story.

STANFORD -- Knowledge gained from nearly two decades of sleep research is now being applied by Stanford University physicians to the treatment of insomniacs and other patients with sleep disturbances.

A Sleep Disorders Clinic, opened recently at Stanford University Medical Center, offers diagnosis and treatment of insomnia, narcolepsy, hyperinsomnia, bed wetting, nightmares, sleep walking, and other afflictions involving the nighttime portion of man's existence.

The new clinic, one of three in the country, is directed by Dr. William C. Dement, a neurophysiologist and leading sleep researcher. Dr. Dement entered the field of sleep research in the early fifties. A that time, the subject was essentially a scientific curiosity pursued by a handful of persistent, sleepy-eyed young men who stayed awake at night to observe others sleep, and to study their brain wave recordings on miles of polygraph paper.

"This research, which has been done with generous federal support, has been well worth it," said Dr. Dement in a recent interview.

"Not only do we have a vastly expanded body of knowledge pertaining to normal sleep in man and animals, but we are able to make accurate and precise diagnoses and initiate effective treatment," he added. "This includes both primary and secondary sleep disturbances, not to mention having a handle on a major portion of the drug abuse problem--sleeping pills and pep pills."

One important early observation made by Dr. Dement and his colleagues is that dreaming in humans and animals occurs mostly during a stage of sleep which appears in humans with monotonous regularity every 90 minutes throughout the night. During these dreaming periods, the sleeper shifts his eyes as if to scan the unfolding panorama of his dream world.

This nocturnal phenomenon, called rapid eye movement or REM sleep, is believed to be essential to well being. Past studies by Dr. Dement have shown that depriving a person of REM sleep can cause sleep abnormalities and mental changes.

Sleep disorders constitute a health problem of some consequence in the United States, Dr. Dement stated. A few years ago it was estimated that Americans were spending in excess of $100 million a year for sleep-inducing prescription drugs. The figure has undoubtedly gone up since then, and it does not include over-the-counter preparations.

Independent research as well as his own studies of over-the-counter drugs raise serious doubts about their effectiveness, he said.

The problem is further complicated by the fact that the science of sleep research is relatively new, and many practicing physicians are not well informed on the subject. As a result, Dr. Dement said, some sleep disorders encountered by doctors are often misdiagnosed and mistreated.

-more-

The story of several young mothers who had experienced postpartum insomnia was cited as a case in point. "A normal condition for many mothers after childbirth, such insomnia is probably nature's way of making sure the mother hears the baby at night," said Dr. Dement.

However, these patients were treated with barbiturates prescribed by their physicians, he related. Soon the mothers developed drug tolerance and the dose was gradually increased. When they came to the sleep clinic, the patients were hooked on barbiturates and complained of acute insomnia. At the clinic, the patients were simply placed on a program of gradual drug withdrawal. After that they slept normally.

The case of the young mothers is of more than passing clinical interest because sleep researchers now know that some sleeping drugs suppress REM sleep while others do not, and the dependency on sleeping pills occurs most readily in the REM-suppressive compounds.

"This is why insomniacs who are given drugs for prolonged periods should be given one of those drugs which produce normal sleep rather than medications which suppress or eliminate the REM phase," Dr. Dement explained.

One of the tasks of the new sleep clinic is to find a precise definition of insomnia. "The term is easily understood in a general sort of way," Dr. Dement said. "But when we attempt to bring some precision into our understanding of the condition, we find it is peculiarly elusive."

He noted the most tangible insomnia which does not qualify as an illness is the sleeplessness induced by an emergency, some duty, noise, or other outside reason.

Dr. Dement believes many people diagnosed as insomniacs are not insomniacs at all. "We must keep in mind the possibility that some patients might be 'cured' if confronted with their own sleep recordings which show they are not having problems with sleep," he said. "Generally such insomniacs will sleep longer in the laboratory than they claim to sleep at home."

True insomniacs who are of special interest to the clinic are people who cannot fall asleep, cannot remain asleep, and cannot get enough sleep, he said.

When patients are referred to the clinic, they are interviewed by Dr. Dement and his staff to determine if their sleep problems are related to mental or physical illness. It is known, for example, that patients with emphysema, heart disease, and ulcers often experience insomnia as a result of their condition.

Patients admitted to the clinic may come in the evening to sleep in the laboratory. To study their patterns of sleep or lack of it, the sleep researchers tape tiny discs to each patient's head that are attached to an electroencephalograph. Tracings on miles of graph paper record brain waves, eye movements, as well as body temperature and heart rate. When drugs are prescribed to improve the patient's sleep, precautions are taken to insure that drug effects are specified.

"One of the first things we try to ascertain is whether or not the patient is going to bed too early," Dr. Dement explained. This can be done by temperature measurement with a special thermometer.

-more-

"It is easier to go to sleep when the body temperature is on the downward phase of the daily cycle--98° or lower," he continued. "That is a sign that the body is at its most inactive state and ready for sleep. It is likely that some insomniacs may improve their sleeping habits by delaying their bedtime."

While insomnia is by far the most common sleep disorder encountered at the clinic, Dr. Dement thinks some headway is also being made in the understanding and treatment of narcolepsy. This condition causes irresistible sleep attacks of relatively short duration, usually less than 15 minutes. It is thought to be a rare disorder although no figures are available on how many people are affected.

"Because we showed that narcoleptic attacks were actually attacks of REM sleep, we were able to predict that drugs such as Tofranil which inhibit REM periods, would be effective treatment," Dr. Dement said.

The case, however, is not entirely clear-cut. Drugs which alleviate the sleep attacks in some narcoleptics fail in others, a finding which revealed that there are two types of narcolepsy--one associated with REM sleep, and another with normal sleep, he said.

While sleep researchers continue to attack the problem of the cause and treatment of narcolepsy, certain things can be done to help these patients, Dr. Dement stressed.

One is distribution of information about the disorder. "Failure to diagnose it properly results in inadequate treatment," he said. "A failure of employers to understand that narcoleptics suffer from uncontrollable sleep results in the firing of seemingly lazy or irresponsible employees who would perform very adequately if they were granted one or two naps a day."

Dr. Dement feels in most instances untreated narcoleptics should not be allowed to drive. Studies have shown that more than 10 per cent of these patients are involved in automobile accidents as a result of dozing off while driving.

One of the strangest parts of the illness in patients suffering from REM-type narcolepsy is the condition known as cataplexy, he said. This consists of brief attacks of muscular paralysis and falling precipitated most often by laughing or becoming angry.

Dr. Dement said it is important for narcoleptics themselves to understand the nature of their apparently strange illness. "Our own patients have been tremendously relieved to learn that they suffer from sleep attacks and not from serious mental or physical illness," he commented.

STANFORD -- The Herbert Hoover Pavilion of Stanford University Hospital reopens its operating rooms this week, to handle primarily plastic surgery, and eye surgery.

A donation of $75,000 from the hospital's 900-member Auxiliary is helping to pay for extensive modernization of the Pavilion's operating facilities.

The kinds of surgery to be done initially in the Pavilion's newly remodeled and equipped surgical suite require only local anesthesia. For the present, all operations requiring general anesthesia will continue to be done at Stanford University Hospital's main center.

When the overall surgery caseload is heavy, minor surgeries contribute to an overcrowded schedule at the University Hospital. (Although the patient census at the hospital has been unusually low in the past few months, the demand for operating room time is increasing.)

Surgery has not been done at Hoover Pavilion, formerly named the Palo Alto Hospital, since Stanford University built a medical center on the campus in 1959. In that year the older hospital, which was built in 1931, closed, and all its personnel and services moved to the new hospital at the main center.

In 1965, the older building was remodeled, the Palo Alto City Council gave it the name of the University's famed alumnus and the area's most widely honored resident, and it was reopened as a pavilion of the new hospital. But its operating rooms were not reactivated at that time.

Three years later in 1968, the hospital of which Hoover Pavilion is a part also received a new name. "Palo Alto-Stanford Hospital Center" was changed to "Stanford University Hospital" when the University purchased the portion owned by the City.

An important feature of patient care at the Pavilion will be that many plastic surgery patients will be outpatients. That is, instead of being hospitalized overnight, they will rest in bed under nursing surveillance in a holding facility for as long as medically necessary, then will be allowed to go home.

Some plastic surgery patients will, however, need overnight or even long-term hospitalization.

Patients admitted for eye surgery will be at Hoover on an inpatient basis. Ophthalmologists will have access to the newest type of cryotherapy unit, for treatment of cataracts and retinal detachments. Cryotherapy is a freezing technique which employs liquid nitrogen.

The way was cleared for reactivation of surgery at Hoover when business offices of the hospital which had been occupying operating room support space were moved to the new Financial Offices Building on Quarry Road in 1969. Support space has also been remodeled and provides an eye examining room, surgical treatment room, an office for the surgical resident, doctors' on-call quarters, and physical and occupational therapy facilities including a Hubbard Tank. The surgical suite itself incorporates two operating rooms, doctors' and nurses' lounges, sterilizing room and storage areas.

The two new operating rooms bring the hospital's complement to a total of 16.

Heart Transplant #27, done January 5, 1971

STANFORD -- Albert Rupp, 36, of San Jose, is in critical condition today after a heart transplant operation last night at Stanford University Hospital.

Rupp, whose home is at 5232 Roeder Road, had to retire from his burglar alarm installation business last summer after a severe heart attack in August.

He and his wife Mary have four sons. They are William, 16; Michael, 13; Philip, 12; and Bryan, 4.

Rupp is Stanford's 27th heart transplant patient. Of the first 26, nine are surviving.

STANFORD--Dr. Edwin William Schultz, professor emeritus of bacteriology and experimental pathology at Stanford University School of Medicine, died today after a long illness. He was 83.

Funeral services will be held at Memorial Church, Stanford, at 11 a.m. Monday.

Dr. Schultz was a member of the Stanford faculty for 34 years, from 1919, to 1953. Noted as a careful teacher, he was also prominent in the field of virology, particularly in some of the preliminary studies of poliomyelitis. He was a charter member of the Stanford chapter of Alpha Omega Alpha (the national medical honor society), served on the American Board of Pathology from 1946 to 1952, and was elected to the presidency of the American Association of Pathologists and Bacteriologists in 1956, taking time out briefly from an assignment abroad to attend the association's annual meeting.

After his retirement from the University in 1953, he was asked to direct an internationally sponsored medical training project at the University of Indonesia at Jakarta, where he served for seven years. This project was established by the University of California, the University of Indonesia at Jakarta and the U.S. International Cooperation Administration, who recruited faculty members from various U.S. universities to work toward alleviating the shortage of doctors in the young republic. Dr. Schultz came as director through the auspices of the China Medical Board of New York, an affiliate of the Rockefeller Foundation.

The help given by the American medical team earned Indonesia's praise and gratitude. The medical school at Jakarta was modernized and greatly expanded, and had tripled the size of its graduating classes by 1960, when Dr. Schultz returned to the United States.

Later he undertook another new assignment, two years as a visiting senior scientist directing the pathology laboratory of the Regional Primate Research Center at Beaverton Oregon. (This, the first of the Regional Primate Research Centers established by the National Institutes of Health, was co-sponsored by the University of Oregon.) He stayed in this post until his final retirement in 1964.

The Stanford emeritus professor was a 1913 graduate of Winona College of Agriculture in Indiana, and held the A.B. degree from the University of Michigan (1914) and the M.D. degree from Johns Hopkins University (1917).

-more-

222--Dr. Edwin William Schultz

He met his wife, the former Anna Francel Roberts, during their student days at Winona College. They were married in 1914. Mrs. Schultz, who lives in Palo Alto, survives her husband.

Dr. Schultz was a member of the Army Medical Corps in France in 1917-18. He spent a year with the American Red Cross, serving in Paris and in Poland prior to joining Stanford.

He was an administrator during 33 of his 34 years on the Stanford faculty, serving as chairman of the Department of Bacteriology and Experimental Pathology (now known as Medical Microbiology) from 1920 on.

In addition to his wife, Dr. Schultz is survived by two sons, Edwin Jr. of Anaheim, California, and Robert Schultz, M.D., of Ft. Myers, Florida, and three grandchildren.

The family request that no flowers be sent. Donations may be made to the Edwin William Schultz Memorial Lectureship in Medical Microbiology being created at Stanford University School of Medicine.

SAN FRANCISCO -- A Stanford University Nobel Prize winning geneticist Tuesday urged citizens to communicate to President Nixon their views of the priority that should be given to health research.

Dr. Joshua Lederberg warned that although the President has signed the Health Appropriation Act for fiscal 1971, he still has the authority to allocate or to withhold the funds.

Under the new appropriation, funds approved by Congress for the National Institutes of Health will amount to $1.6 billion. According to Dr. Lederberg, this amount is a little over what is needed to hold the line, after several years of serious restraint in health research.

"This is not a partisan issue--many previous administrations have used this prerogative to save tax moneys in favor of programs that had stronger political clout," he said.

Acknowledging that President Nixon has not yet expressed himself, one way or the other on this issue, Dr. Lederberg cited evidence that funds approved by Congress for health research may be sliced off without very serious consideration.

"It is disconcerting," he said, "that some of the President's advisers have commented in opposition to the increase in research funds in their testimony before Congress.

"Their arguments are based on cliches that reflect serious ignorance of the actual mode of training physicians, of the relationship of research and clinical training in the medical schools, and of the desperate financial plight of many schools when we have unprecedented needs for more skilled professionals to clear up a pernicious scarcity market."

Dr. Lederberg stressed that medical schools have been built with support of health research. "It would be better if medical education were supported directly on its own merits, rather than merely as a spillover benefit of subsidies for research, but choking the source will dry up the entire stream," he said.

Dr. Lederberg made his remarks in a statement prepared for delivery at a press conference at the University of California Medical Center. The conference was one of three held Tuesday in New York, Chicago, and San Francisco under the auspices of the National Cystic Fibrosis Research Foundation, New York. Nobel Laureates James Watson and George Beadle were among the participants in New York and Chicago.

"Unfortunately, health research has no particular lobby or political constituency," Dr. Lederberg said. "The people best equipped to report on the impact of budget cuts are those, who like my colleagues here, are deeply involved in it.

"We command very few votes and, of course, we can be accused of self-interest in pleading for these funds, as can anyone whose work is in public service."

He said the scientists' pleas will be useless unless the public--those whose health is at stake, express themselves directly--in letters to the President, to Congressmen, and to newspaper editors.

Dr. Lederberg said the confusions and conflicts of our public policy on health research exact their toll in various ways. The cost of uncertainty in not knowing about seafood contamination by mercury, radiation health hazards, food additives, and pesticides may be at least as high as the NIH budget.

He said the public pays the price eventually by taking expensive precautions against these hazards out of sheer ignorance.

STANFORD -- Dr. John R. Hogness, president of the newly-formed Institute of Medicine in the National Academy of Sciences, will deliver the keynote speech at the dedication of the new $560,000 Psychiatry Clinic Building at Stanford University Medical Center, Thursday, December 9.

The public ceremony marking the official opening of the adult and child clinic facility will begin at 2:30 p.m. in the Dean's Courtyard at the School of Medicine. Dr. Hogness will be introduced by Dr. Clayton Rich, dean of the School of Medicine.

This will be Dr. Hogness' first public statement on mental health since assuming the presidency of the Institute last August.

A 1946 graduate of the University of Chicago School of Medicine, Dr. Hogness served as an administrator and faculty member at the University of Washington for 21 years before accepting his present position.

After six years as medical director of the University Hospital, Dr. Hogness was appointed dean of the School of Medicine and chairman of the Division of Health Sciences in 1964. He became executive vice president of the University in 1969. From 1970-71, he served as chairman of the Board of Health Sciences and director of the Health Sciences Center, composed of six colleges, two hospitals, and four health care and research centers.

Following the dedication ceremonies, an open house will be held for the public in the new building and also at the Department of Psychiatry's inpatient facility at Hoover Pavilion.

The new two-story redwood building was added to give the psychiatric outpatient program at Stanford space it urgently needed and to provide a more pleasant, informal setting for individual and group therapy sessions. Completed in mid-August and now being landscaped, it houses the department library and staff offices, group therapy rooms, and Adult and Child Psychiatry Clinics.

"Between the adult and child clinics, we'll be able to handle close to 20,000 patient visits per year," said Dr. Alan Rosenthal, director of the Child Psychiatry Clinic. "Every staff member has an office, whereas in the past most of our residents had to share offices. Now everyone is free to see many more patients."

Located just south of the main center, the new facility is adjacent to the Edwards Building, which formerly housed overcrowded clinics, department offices and laboratories.

The removal of the clinics and offices from Edwards has freed space for the broad interdisciplinary study of violence and aggression at Stanford, directed by Psychiatry Department chairman Dr. David Hamburg. The balance of the vacated space will be department laboratories for Psychiatry and Biochemistry.

Stanford's psychiatric program employs the "team treatment" concept, in that faculty psychiatrists, social workers, residents and psychologists are all involved in developing therapy for clinic outpatients. The floor plan in the new building facilitates this approach. -more-

"We designed the new clinic floor plan so that teams of doctors are physically located together in clusters of offices," said John Hornback, resident architect at the Medical Center. "Groups of four or five offices are situated around small waiting rooms."

The clustering of offices provides waiting patients with more privacy and reduces the amount of corridor space.

"In the new building we avoid the long walk down a corridor, which sometimes has a 'last mile' feeling for patients," said Dr. Peter Rosenbaum, director of the Adult Psychiatry Clinic.

The building also features a two-story covered courtyard, equipped with sliding panels on two sides for circulation.

The 18,000 square foot structure was designed with economy and flexibility in mind, according to Hornback.

"Outpatient psychiatric therapy doesn't have to take place in a high cost, concrete structure," he said. "With no need for laboratory utilities, we could construct a low cost facility.

"In terms of flexibility, all the interior partitions are non-load bearing and can be easily moved. The carpet and ceiling are continuous, so when a partition is moved, the room still looks finished. Additionally, the building can be taken apart by 30-foot sections and relocated by housemoving methods."

Hornback's staff members Jim Brenner and Ray Rooker carried major responsibility for designing the building, along with Stanford Hospital's Engineering Department. Welch Construction Company of Mountain View was the builder.

Funds to finance the building came from private sources. Plaques will honor the gifts of two major donors--John C. Cosgrove and Mrs. George A. Winzer. The upper floor of the building will be named the Emilie Dohrmann Cosgrove Psychiatric Clinic, in honor of Cosgrove's late wife, who was a member of the class of 1933 and a former trustee of the University. One of the wings on the first floor will be called the Frances Winzer Wing in honor of Mrs. Winzer.

Four members of the Stanford faculty were recently elected to membership in the Institute of Medicine, including Dr. Robert A. Chase, professor and chairman, Department of Surgery; Dr. Hamburg; Dr. Donald Kennedy, professor and chairman, Department of Biological Sciences; and Dr. Joshua Lederberg, professor and chairman, Department of Genetics.

Dr. Hogness' brother, Dr. David Hogness, is a professor of biochemistry at Stanford.

STANFORD--Similarities in the landscapes of Turkey and California emerge in the paintings of Susan Wexler, which are being exhibited at Tresidder Memorial Union on the Stanford campus through March 25. (Hours the Union is open are 8 a.m. to 10 p.m. Mondays through Fridays.)

Susan, a self-taught artist, is married to assistant professor of radiology at Stanford University School of Medicine Dr. Lewis Wexler. They spent two years in Ankara while he was serving with the U.S. Air Force there.

She says the experience influenced her painting to a great extent. "I became interested in the look of 'people in relation to the land,' " she says, "whereas before I tended to see either/or."

The artist, who took college degrees in English literature at Syracuse and Columbia, began painting 10 years ago. The inspiration, she says, comes from her reaction to places: "It's the way a place makes me feel."

The viewer at the exhibition will note akin responses to the California and Turkish countrysides, which she explains "resemble each other as far as sun and light, and a predominance of golds and earthy colors are concerned." There are several California subjects in the show: her (impressionistic) view of a Los Altos apricot orchard, the live oak-studded hills, Carmel, Pt. Lobos, Monterey, High Sierras forests as seen at Grant Lake.

There are some nudes, a portrait of a young bearded man, an abstract or two, and very few still lifes rounding out the show. The media demonstrate versatility--oil, acrylic, pastel, watercolor and drawing.

Mrs. Wexler is the mother of three sons, aged 2-1/2, 8 and 10. She is a volunteer art teacher for fourth-, fifth-and sixth-graders at the Lucille Nixon Elementary School at Stanford.

STANFORD -- Stanford University Hospital has announced that it will supplement its daytime tours for expectant parents with one evening tour a month.

The later hour, arranged as a convenience for the fathers, who more typically cannot get away during the working day, will enable the couple to visit the hospital together.

Evening tours will be held the third Tuesday of each month from 7 to 8:15 p.m. Miss Marcie Barton, R. N., of the hospital's perinatal unit, will guide the tour groups, which will be limited to 20.

Regular daytime tours for expectant parents are held (most) Wednesdays at 11 a.m. Fathers are also welcome on Wednesday mornings.

To ensure a place, couples are asked to make reservations by calling the Office of Public Events, 321-1200, Ext. 5594, six to eight weeks in advance of the date the baby is due, so that they can visit the hospital approximately one month ahead of the due date.

This month the evening tour is March 16.

EDITORS: Copies of STANFORD M.D. available on request if not included with the story.

STANFORD -- A Stanford University psychiatrist, who says humor has received insufficient scientific attention, has launched a study of laughter and its role in health.

"In most studies dealing with the positive human emotions, humor has played a minor role compared to love, affection, and desire," says Dr. William F. Fry, Jr.

"The state of our knowledge about the physiology of mirth is similar to the familiar iceberg--we know only the upper fraction of the whole," he adds.

Fry, an associate clinical professor of psychiatry, says he found it difficult to do his research by telling volunteers jokes and then asking them to rate them in order of funniness. That approach was too subjective. So he turned his attention to the physiology of mirthful laughter.

"My plan was to develop enough information about the happenings of various bodily systems during mirth that a physiologic model for laughter could be devised as an objective tool for humor research," Fry reports.

The studies he conducted thus far have included the effects of mirth on the heart rate and the electrocardiogram. He also examined laughter as a respiratory phenomenon, and the effects of mirthful laughter on the oxygen saturation levels of the blood.

Two Palo Alto electronics engineers, Con Rader and Paul Stoft, assisted in the studies in which Stanford people took part as consultants or volunteer subjects.

The volunteers were wired to machines which measured their physical responses as they listened to humor stimuli (taped jokes from professional and amateur sources.)

Here is what Fry found based on a report of his work in the current issue of STANFORD M.D., the magazine of the Stanford Medical Alumni Association:

. Laughter causes a complete disruption of the normal respiratory cycle. Recovery following laughter is a gradual--in excess of 10 seconds on occasion--return to normal breathing.

. Laughter consists of varying mixtures of expiration, inspiration, and interval pausing. These components have characteristics which give each person a generally unique laughing style.

More rapid-than-normal heartbeat (tachycardia) of varying degrees is associated with laughter. Rates of over 120 were found with more prolonged and intense laughter. The heart rate studies suggest a physiologic reflex effect on heart activity rather than the rapid heartbeat being a response to the emotion involved, Fry comments.

"This is research in process," Fry notes. "There are other basic areas that beg investigation: for example, brainwaves, blood flow rate, body temperature, and concentrations of body chemicals will be studied in the future."

-more-

These basic studies have also suggested ideas for clinical research.

"People can suffer cardiac decompensation (heart attack) during sexual intercourse, dreaming, while driving on the freeway, as spectators in sports events, watching TV," says Fry. "To my knowledge, there is no literature detailing cardiovascular jeopardy during mirth--this despite the massive muscular activity associated with laughter, the rapid heartbeat, and adrenal gland activation."

Another area of study has to do with lesions of the upper gastrointestinal tract. "We know, from earlier studies of humor's physiology, that the diaphragm is much involved in laughter as are the muscles of the abdominal wall," Fry writes. "The spasmodic quality of laughter is also evident from everyday observation."

He comments that in view of this there may be clinical implications of laughter for esophagitis, hiatal hernias, and gastric and duodenal ulcers. Laughter could also contribute to strokes in those who are susceptible, Fry notes, and he points to an already documented fact in medical literature--laughter's contribution to the precipitation of seizures in epileptics.

Fry's research is not limited to the physiologic level. It is also concerned with psychologic and sociologic aspects of humor as a basic emotion as well as its evolution.

"How much farther down the evolutionary tree mirth goes is a matter of conjecture," Fry says. "Some hint comes from humor's consistent impact on several basic physiologic systems which must have had origin at the beginning of mammalian life, at least."

Three years ago, Fry was skeptical of scientific reports concerning the presence of mirth, or laughter, in chimpanzees and gorillas.

But he was argued out of his recalcitrance by the work of Dr. Lawrence Pinneo of the Stanford Research Institute in Menlo Park.

"During the process of numerous demonstrations--he even locked me in a cage with three delightful but inexhaustible young chimps--he has turned me around to the point I am strongly convinced that chimps have a sense of humor and do laugh in a very human fashion (or perhaps that should be vice versa)," Fry wryly comments.

Additionally, Pinneo and Fry with the assistance of pediatrician-photographer Sheldon Woodward, Menlo Park, are exploring the manifestations and roles in various species of the social grimace, grin, or smile.

"Consideration of a common progenitor for the social grimace and a human smile is of course speculative," Fry writes. "But it does touch rather resoundingly on the question of a dynamic relationship between humor, hostility, and anxiety--a question which has received much attention in human psychology."

###

Editor's Note:

Fry is author of a book, SWEET MADNESS: A STUDY OF HUMOR (1963). He is also director of the Gelotology Institute, San Francisco. Gelotology, a word coined by linguist-anthropologist Edith Trager, formerly of San Jose State College, originates from the Greek root, gelos: laughter. It is used to designate the science of laughter.

STANFORD -- Doctors can watch a movie of the beating of a patient's diseased heart--identifying dead spots or scar tissue in the heart wall, aneurysms (bubble-like projections of the heart muscle), and other malfunctions--with a computer method devised by a NASA-Stanford University team.

The system, which is still under development, would improve on current complex diagnostic methods by providing a simple means of viewing the heart in action. Figuratively, it allows doctors to "walk around" the isolated beating heart, viewing it from any desired angle. They also can stop the heart at any desired point of expansion or contraction and can play the picture back and forth for many cycles.

The system projects a three-dimensional animated cartoon-like image of any desired chamber of the patient's heart, in lines of light on a computer display screen, similar to a television screen. The animated display is derived from two-dimensional "X-ray movies" made by injecting X-ray contrast dye into the desired heart chamber.

Scientists and doctors from NASA-Ames Research Center, Mountain View, California, and the cardiology division of Stanford University Medical Center, have worked together on the system.

It appears that the method may be a major advance for the physician to determine the patient's need for heart surgery, coronary artery grafts, and treatment of various heart conditions. Heart disease is the leading cause of death in the United States.

The system's animated display is exact enough to show dead sections of the heart wall about the size of a nickel (two centimeters), details of large malfunctions, and holes between heart chambers. Combined with standard clinical measurements of blood-flow per heart beat, it can measure inefficient pumping by heart chambers. It will also help to identify leaky valves and shows the severity of valve damage.

This system will allow further validation of a sonar-like system for testing heart function which is also under development by this group of scientists. These sonar systems would allow examination of the healthy hearts of astronauts, pilots and ordinary citizens, using a simple sensor placed on the chest.

"The Ames animated display system seems to be an important advance in the diagnostic tools for studying heart disease," comments Dr. Donald C. Harrison, chief of the Division of Cardiology at Stanford, which is doing the clinical work on the project.

-more-

New Diagnostic Tool for Heart Disease/NASA-Stanford

222

"While X-ray examinations of hearts as they beat are currently in use," says Ames' Dr. Harold Sandler, originator of the system, "X-rays are two-dimensional and hard to interpret because of the various other body structures in the same picture."

The value of the method for doctors is that it eliminates all irrelevant details. For example, it can show the complete interior surface of the beating left ventricle (the heart's main pump) on the lighted display screen and nothing else. The system can do the same with the right ventricle and the two auricles (intake pumps).

Since the animated displays are a form of computer readout, they can be transmitted to doctors at distant locations by an ordinary telephone line, and recreated on a computer display screen.

The displays are derived from X-ray movies, plus a computer program based on intensive research in heart configurations and dimensions, plus new three-dimensional computer display techniques. Daryl Rasmussen, Ames Research engineer, developed the mathematical and computer techniques, using data gathered by Dr. Sandler during six years of work at Ames on heart chamber dimensions and means of measuring them.

Doctors first take the X-ray movie, known as an angiogram. To do this, they inject a dye opaque to X rays through a catheter into the patient's heart. The X rays then outline the selected heart chamber in cross section as it expands and contracts.

Stanford cardiologists working under Dr. Harrison's direction take two sets of X-ray movies at right angles to each other, at 60 frames (pictures) per second.

Obtaining the X rays may be difficult since injection of the angiographic dye itself changes the function of the heart and makes only the data from two heart beats acceptable for analysis. However, the researchers use a variety of independent measurements to make sure the two beats used are exactly typical. Validation of the technique by other independent means is now being accomplished.

From the two X-ray movies, the computer constructs the animated display. The entire sequence of movie frames, each one containing the heart chamber outline, is traced on a computer input screen, and is retained in the computer memory. The computer program then mathematically projects the two views of the heart chamber back into space. From these it reconstructs the chamber. This three-dimensional construction is also stored in the computer memory for analysis and display.

The technique allows the computer to calculate the changing positions of the entire interior surface of the heart chamber in question, so the moving heart chamber can be seen from any point.

The computer program is based on studies of the exact proportions of hundreds of normal and abnormal human hearts gathered by Dr. Sandler from autopsies, and studies of patients with heart diseases of various types.

The two stored beats are repeated over and over by the computer, allowing doctors to study the heart in action for any desired period of time.

STANFORD -- Charges that a Chicano faculty member in the Stanford Medical School was denied tenure for racial and political reasons are unfounded, Acting Dean John L. Wilson said Wednesday (April 7).

The charges were made by five Chicano student- and employee-related organizations in an article in The Stanford Daily.

The faculty member is Dr. Jose Aguilar, a neurosurgeon who had a three-year appointment as an assistant professor of surgery.

According to faculty appointment procedures of the Medical School, Dr. Aguilar was notified November 1970, that he would not be reappointed, Dr. Wilson explained.

The decision was made by an eight-member committee of the senior faculty of the Department of Surgery.

Dr. Aguilar's case was reviewed again in March 1971, at his request, and the decision not to reappoint him was upheld, Dr. Wilson said.

Dr. Wilson said that Dr. Aguilar is not the only assistant professor who did not get a reappointment. Funding problems, research projects that do not pan out, faculty productivity, or changing departmental needs count heavily in the reappointment of faculty, he commented.

The medical school dean said the charge of racial bias published in the Stanford Daily with respect to Dr. Aguilar was unjustified.

He said the Provost's office has investigated this case and no irregularities were discovered in the decision-making process.

The article in the Daily was signed by the National Chicano Health Care Organization, Stanford Chapter of the Student National Medical Association, Alianza Latina (a Stanford Hospital employee group), the Black Liberation Front, and Stanford Medical Student Association.

STANFORD -- The Stanford University Hospital Wednesday night (APRIL 7) made a detailed response to questions concerning its personnel policies, and the firing of Sam Bridges, a Black employee at the Hospital.

The questions were raised by supporters of Bridges who rallied at the Medical Center yesterday to protest his firing and to demand more rights for workers.

Among the demands were: workers' rights to criticize administration policies, to organize, to have grievance rights from date of hiring and peers present at all grievance procedures.

The hospital was also asked to adopt an affirmative action program to hire and train minorities and to reinstate Bridges with back pay.

In an open letter to the Stanford community, Dr. Thomas A. Gonda, hospital director, stated: "Mr. Bridges was informed of the opportunity to file a grievance and was given a copy of the Hospital's grievance procedure and of the rules of conduct with those violations pertaining to him underlined. He has not chosen to bring his case before the grievance committee."

Dr. Gonda also wrote:

. "All employees have the right to criticize administration policies. If there are instances in which that policy has been violated, I would appreciate having the evidence brought to my attention."

. "Employees are free to decide if they wish to join unions. The Hospital was involved in a union election in 1967, and union organizing activities have been held regularly ever since."

. "Stanford University Hospital has an affirmative action program, and is completing its documentation. For the past two years Stanford hospital has had a Black advisory committee elected by Black employees. More recently the Alianza Latina, composed of most of the Spanish speaking employees of the Medical Center has been formed. These groups have been actively involved in the implementation of...the program."

On the question of grievance rights from date of hiring, Gonda wrote: "Present hospital policy is ambiguous on this point. Our practice, however, has been to make grievance procedures available to all employees regardless of length of service. I will take steps to clarify the policy manual on this point."

Dr. Gonda noted peers can be present in initial grievance proceedings, as well as in later stages.

STANFORD -- Making a strong plea for greater community control over medical care, Dr. Jose Aguilar told 250 persons at a Thursday noon rally at the Stanford Medical Center that from a personal standpoint "there isn't anything at stake" if he fails to receive a tenure appointment at the University.

"If I fail to get tenure, I'm 'doomed' to a $40,000 or $50,000 job by going out into private practice.... I don't have to be afraid of the Establishment. My referrals would not come from white doctors," he added. A neurosurgeon, he is the sole chicano on the Medical School faculty.

Active in recruiting chicano medical students to Stanford, Dr. Aguilar also works with the People's Medical Center in Redwood City. He said his referrals would come from the community, because when chicanos look for a physician sympathetic with their problems, "the only one around is me."

Noting the heavy federal support of medical activities at Stanford, he suggested that "we have to get our share" for the minority communities. Blacks and chicanos should set the policies for health care in their own communities, he indicated.

Because of the lengthy training required for physicians, he added, it could take 10 to 20 years before blacks and chicanos again could "take up the issue of tenure" for racial minority members seeking careers as physician-professors.

Several medical students and employees strongly endorsed Dr. Aguilar's work at the School. Paul Williams, sole minority student in the medical Class of '73, said "Academic excellence is necessary for minority students, but not sufficient," emphasizing the need for the personal example and guidance of Dr. Aguilar.

In a similar vein, Bertha Gonzalez, a first year medical student, said the School's research is "excellent" but it "tended to ignore the value of good clinical teachers."

Speaking in Spanish, a third student received wide applause when he said that the protest group was not allied with communists or other radicals, but were present "because we're chicanos."

Expressing his appreciation for the turnout and support, Dr. Aguilar said "Somehow all my life--I'm 44, now--I've been hearing someone tell me I'm half-assed good. After hearing that for so long, I'm almost inclined to believe it....

"All of a sudden now there's good for me not to believe what other people tell me--that I'm incompetent, etc.--because I know that somebody out there loves me."

An assistant professor of neurosurgery at Stanford since 1965, Dr. Aguilar was notified in November that he would not receive a tenure appointment. In a statement Wednesday, Acting Dean John L. Wilson of the School described as "unfounded" charges that tenure was denied for racial and political reasons.

STANFORD -- About 50 persons continued to occupy an administrative hallway and offices in the Stanford University Hospital Friday morning, protesting the firing of a Black employee.

There was no interference with patient care. But locked doors to administrative offices in the area were opened and access to the hallway itself was restricted to doctors, patients, and demonstrators.

A Viet Cong flag and a large Venceremos banner decorated the area. Hospital Director Thomas A. Gonda met with a group late Thursday night.

At 12:15 a.m., Acting Dean John L. Wilson of the Medical School, and executive administrative officer of the Medical Center, warned the demonstrators that they were disrupting and said he would seek legal counsel. Police were not called, but hospital security officers continued to observe the area.

Dr. Wilson said he did not see any necessity for prolonging the sit-in, since discussion of the case would continue. But the group decided to remain. Several meetings have been scheduled this morning, including one between the Black Advisory Committee, an employee group, and leaders of the demonstration. Yesterday, the BAC issued a statement indicating their investigation had shown the employee dismissal was for cause.

If the discharged employee, Sam Bridges, were to initiate a grievance procedure, they said their group would seek to insure "fair and impartial treatment."

FOR IMMEDIATE RELEASE

STANFORD - MOre than 50 demonstrators, some swining clubs, injured 13 police add caused an estimated $100,000 property damage to an administrative office area at the Stanford University Hospital late Friday, April 9, when Palo Alto police broke through barricades to end a 30-hour sit-in.

Six officers were treated at the hospital emergency room, where one was admitted for surgery on an injured hand. Four other persons were treated and released there.

There were ~~at least~~ about 20 arrests, including three juveniles. A preliminary check by University officials indicated only ~~three~~ four were students, faculty or staff members.

The demonstrators, who were protesting the dismissal of a black employee, barricaded themselves between two large glass partitions in the second floor before police came.

They were warned they were subject to arrest and given five minutes notice to leave. None did.

Palo Alto Police Chief James Zurcher told the demonstrators, "we'd like to do this as peacefully as possible." A voice inside replied, "There's a lot of expensive stuff in here and we're going to get it. People out there are going to get hurt."

When police used a wodden battering ram on heavy glass doors, the demonstrators turned on a fire hose and poured water on them. Officers squirted a chemical through the broken door and demonstrators threw ashtrays and other objects at officers.

At 6:37 p.m., when police pulled down the doors at one end of the corridor, and climbed over the barricade, many demonstrators using clubs, overwhelmed a nine-man squad blocking the other end of the corridor. Many protesters escaped out office windows, climbing down walls from the second floor.

The offices were a scene of absolute devastation. Desks, chairs, and metal file cabinets were turned over or piled on top of each other. Files and books covered the floor, as did shredded furniture. Phone wires were hung out the windows and the firehose was cut.

Campus police reported there were 11 false fire alarms, five bomb threats, and two trash fires following the hospital incident.

Chief Zurcher said 65 Palo Alto police were deployed, with an additional 110 officers coming to the hospital under a mutual aid agreement.

MORE

Commenting on the issue which led to the sit in, Acting President William F. Miller said that "before the sit-in began, the community was informed that the hospital agreed with five of the six demands made on it.

"On one, the rehiring of Sam Bridges, the answer on Thursday morning was that grievance procedures are available to him if he wishes to use them. That answer still stands. If Mr. Bridges wants to file a grievance, he can be assured of a full and fair airing of the facts of his case."

The demonstration began early Thursday afternoon, when about 70 demonstrators occupied the hallway, unfurling a Viet Cong flag and a Venceremos banner. Soon after, they were asked to leave, but did not do so. At 12;15 a.m. Friday, Acting Dean John L. Wilson of the Medical School, executive administrative officer of the Medical Center, warned the demonstrators they were disrupting and said he would seek legal counsel. Police were not called, and 50 demonstrators remained there.

Friday morning the Stanford Daily published a statement from the Black Advisory Committee, a hospital employee group, stating that Bridges "was terminated because he was not doing the job he was hired to do, and therefore putting an added burden on his co-workers." The BAC said it would insure Bridges "fair and impartial treatment" if he initiated a grievance hearing.

Dr. Thomas Gonda, hospital director, met for three hours with the demonstrators at his occupied office late Friday morning and early afternoon, reiterating similar assurances. He did not agree to reinstate Bridges.

Following a joint meeting with the Black United Front which led the demonstration, and a review of the case, the BAC recommended that Bridges be rehired and retroactively reimbursed for total time loss.

Dr. Gonda held further discussions with Medical Center officials and William F. Miller, acting president of the University during the absence from campus of Richard W Lyman. In a statement delivered to the demonstrators at 4:30 p.m. Miller said that he and Dr. Gonda agreed there could be no conclusion reached on the composition and dates for a grievance procedure while the occupation continued.

Shortly thereafter, the demonstrators voted to remain in the building until Bridges was rehired, indicating they were aware of the possibility that Palo Alto police would soon arrive. They then sealed both entrances to the hallway and erected barricades.

After the incident, Acting President Miller said his prime concern was "how to end the occupation with the least possible danger to patient care services and least possible risk to patients."

"So long as there was a reasonable chance that Dr. Wilson and Dr. Gonda might persuade the people involved to leave voluntarily, I was prepared to refrain from asking for police assistance. However, disruption of hospital functions could not be allowed to continue for long, and when it became clear this afternoon that furth r discussion would not be productive, I asked the Palo Alto police for assistance

President Lyman and Palo Alto City Manager George Morgan made separate visits to the hospital Friday night, surveying the damage. ###

At 12:30 a.m. Saturday, three molotov cocktails were thrown at a PG&E substanion on campus. There was no damage. There was scattered trashing on campus, with Hoover Library and the Varian building among those hit. Dem nstrators inside the hospital had urged supporters outside to "go out and trash."

Cowell Student Health Center said no one had been treated there as a result of the hospital incident. ####

STANFORD UNIVERSITY MEDICAL CENTER

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

STANFORD--Activities at Stanford University Hospital were back to normal Saturday (April 10). Three main entrances to the hospital are open and tight security is maintained.

Employees have reported for work as usual.

Faculty and administrative staff are scheduling meetings with small groups of Medical Center employees and students. One meeting has been scheduled by the Black Advisory Committee, a hospital employee group, at 9:30 a.m., Monday in front of the Medical School.

The Hospital suffered an estimated $100,000 damage when police were called to end a 30-hour occupation of the administrative offices.

The demonstrators, who were protesting the dismissal of a Black employee, barricaded themselves between two large glass partitions on the second floor before police came.

The demonstration began early Thursday afternoon, when about 70 protesters--all nonemployees--occupied the hallway, and demanded an answer to demands presented to the hospital administration earlier.

Before the sit-in began, the community was informed that the hospital agreed with five of the six demands made on it.

These included the right of workers to criticize the administration, organize, and have the right to grievance procedures from the start of employment.

On one of the demands, the rehiring of Sam Bridges, the answer on Thursday morning was that grievance procedures are available to him if he wished to use them. If he wanted to file a grievance, he could be assured of a full and fair airing of the facts in his case.

On Friday Hospital administrator, Dr. Thomas A. Gonda met with the Black United Front which led the demonstration.

After many meetings with the demonstrators, asking them to leave, university and medical center officials concluded that there could be no agreement reached on the composition and dates for a grievance procedure as long as the occupation continued. Shortly, thereafter, demonstrators voted to remain in the building until Bridges was rehired.

Officials then decided that disruption of vital hospital functions could not be allowed to continue, and called police.

###

Mailed Saturday, April 10, 1971

Handed to SUH 4-12-71 by Jim Cheatham

We request that the demands listed below be considered as absolute and they are non-negotiable. Further, these demands presented should be resolved by the date, Wednesday 14, 1971.

1) All charges related to all persons who were arrested in connection with the non-violent demonstration held at Standord University Hospital, April 9, 1971. Notwithstanding, all legal fees incurred during this demonstration shall be paid in full by Stanford University.

2) Any persons who received any form of injury because of their direct or indirect involvement in the demonstration should have all medical expenses paid in full by Stanford University.

3) Sam Bridges shall be reinstated and reimbursed retroactively from date of termination.

4) Dr. John L. Wilson, active Dean of the Medical School, will be asked to resign.

5) Mr. Warren Thorpe, Assistant Chief Engineer, will be asked to resign.

6) There will be created a separation of the Stanford University and Medical Center with each having its own autonomy.

7) The Black Advisory Committee cannot function in an advisory capacity without having the power to represent the total Medical Center which includes both the Stanford Hospital and the Stanford School of Medicine.

8) The decision-making apparatus must exist only with horizontal authority. This restructuring is imperative.

The above demands have been setforth by the Black Advisory Committee in conjunction with students in the Stanford School of Medicine.

cc: Dr. John L. Wilson, Dean - Stanford School of Medicine
Dr. Thomas A. Gonda, Director - Stanford University Hospital
Dr. Milton R. Burnfield, Assistant Professor of Pediatrics
Mr. James E. Simmons, Assistant to the President

OR IMMEDIATE RELEASE

STANFORD - Bail has been set at $1,000 each (pending arraignment) for 22 persons arrested in Friday night's clearance of the Stanford University Hospital sit-in.

Leaders of the Black Students Union, at a campus news conference, warned that "in the face of brutal tactics employed by Stanford University against peaceful demonstrators, we cannot allow business to be carried on as usual until all our demands are met."

These include reinstatement of Sam Bridges, a black hospital employee whose firing led to the demonstration, and amnesty for all those involved in the protest.

Thirteen police and at least seven arrestees were among 22 persons injured in the Friday night incident, which also resulted in $100,000 damage to administrative offices at the hospital. One policeman was hospitalized.

Bail for those arrested was set Saturday afternoon by Palo Alto Municipal Court Judge Barton Phelps and Santa Clara County Superior Court Judge William Ingram.

At the court hearing, Deputy District Attorney Dennis Lempert called for ,000 bond each. Norton Tooby, defense attorney, argued for release on recognizance until arraignment, with provisions which would bar a repetition of the incident.

John Schwartz, presidential assistant at Stanford, said the University had no objection to Tooby's suggestion or to setting bail at an amount defendants could reasonably be expected to pay,

The judges released one defendant, who is pregnant, on her own recognizance. They said students, faculty, and other employees arrested were allowed on campus only in connection with their legitimate, useful purposes, pending arraingnment. Other defendants, not connected with the University, were barred from entering campus until arraignment.

The defendants may insist on arraignment within 72 hours of booking.

Black students attending the hearing warned that conditions on campus were tentially explosive.

In their statement, the BSU leaders said: "It should be understood that... entrance into Stanford Hospital and occupation (of a hallway and offices) were not disruptive of hospital functioning.

"Doctors and patients were allowed to carry on as usual.

"It should also be understood that the majority of the demands of the workers were met prior to the police intervention and that, when police moved to clear the building of demonstrators, there were only two unsettled issues," the rehiring of Bridges and amnesty.

They charged that Leo Bazile, former chairman of the BSU, was singled out for "racist attack" by the police when the hospital was cleared. ###

APRIL 12, 1971

FILE COPY

uncorrected copy

April 12, 1971

TO: Medical Staff and Students

FROM: John L. Wilson, M.D.
Acting Dean, School of Medicine

SUBJECT: Sit-in at the Stanford University Hospital on April 8-9, 1971

On Tuesday, April 6, a noon rally was held on the lawn near the Medical Center by the Black United Front. The BUF is said to be a coalition of the Black Liberation Front, the Black Workers Caucus and representation from the Black Student Union. The Front was organized as a response to the dismissal of Mr. Sam Bridges, a hospital employee, and the laying off of workers at Tresidder. Following the rally on April 6, over 100 persons went to the office of Doctor Gonda, Director of the Hospital, and presented to him a list of 6 demands. They stated that they would return for a reply to these demands at noon on Thursday, April 8. As far as is known, the groups presenting the demands included few if any Hospital employees.

On April 9, another noon rally was held following which about 50 persons went to the office of Doctor Gonda stating that they expected to receive from him, in person, the reply to their demands. The reply had been printed in the Daily on that morning and copies of it were handed to the group. The demands, with Dr. Gonda's responses to them, are printed below:

1. "Workers must have the right to criticize administration policies from the date of hiring without intimidation."

   All employees have the right to criticize administration policies. In addition, there are regular opportunities of communicating employee views to the administration. If there are any instances in which that policy has been violated, I would appreciate having the evidence brought to my attention.

2. "Workers must have the right to organize a union which represents the workers' interest."

   Employees are free to decide if they wish to join unions. The Hospital was involved in a union election in 1967, and union organizing activities have been held regularly since then.

3. "Workers must have grievance rights from date of hiring."

   Present Hospital policy is ambiguous on this point. Our practice, however, has been to make grievance procedures available to employees regardless of length of service. I will take steps to clarify the Policy Manual on this point.

4. "Workers must have the right to have peers present on all grievance procedures."

   While the grievance procedure does not explicitly provide for the presence of peers at the early steps, our practice has been to allow it as is expressly set forth in later steps of the grievance procedure.

5. "The rehiring of Sam Bridges with pay for time loss."

   Mr. Bridges was informed of the opportunity to file a grievance and was given a copy of the Hospital's Grievance Procedure (Section 525) and of the Rules of Conduct (Section 500) with those violations pertaining to him underlined. He has not chosen to bring his case before the Grievance Committee.

6. "Stanford Hospital must adopt an Affirmative Action Program."

   Stanford University Hospital has an Affirmative Action Program, and is in the process of completing its documentation. For the past two years Stanford University Hospital has had a Black Advisory Committee selected by Black employees. More recently the Alianza Latina, composed of most of the Spanish speaking employees of the Medical Center, has been formed. These groups have been actively involved in the implementation of the Hospital's Affirmative Action Program.

All of the above demands, with the exception of the rehiring of Mr. Sam Bridges, were reported by Dr. Gonda to be already part of Hospital policy or positive action on them is imminent. The rehiring of Mr. Sam Bridges with pay for time lost was identified early as the chief issue. The Black Advisory Committee, consisting of Black Hospital employees, issued the following statement giving the reasons for the firing of Sam Bridges and their support of the action taken:

MEMORANDUM

TO: Hospital Employees

FROM: The Black Advisory Committee

SUBJECT: OUR STAND ON THE SAM BRIDGES CASE

We, the Members of the Black Advisory Committee, upon reading the charges made by Mr. Sam Bridges, did, in fact, conduct a thorough investigation regarding his dismissal.

The investigation disclosed the following facts.

1) On several occasions his co-workers complained that Mr. Bridges was not doing his work and that they had to carry his workload as well as their own.

2) On two particular occasions he verbally abused - 1) a co-worker because he was questioned about some work he had not done, and 2) a Security Guard because he was told that he had to put money in a parking meter.

3) He was found asleep on one occasion in the "Brown Bag" room while he was supposed to be working.

4) He was counselled about his work performance on at least three different occasions due to complaints by his co-workers.

5) He was observed on campus several times while he was supposed to be working.

The Black Advisory Committee can present evidence to substantiate these facts. It was our conclusion that Mr. Bridges was terminated because he was not doing the job he was hired to do, and therefore putting an added burden on his co-workers.

Had Mr. Bridges, after being told about the grievance procedure, chosen to take his case before the grievance committee, this Committee would have insured him fair and impartial treatment.

4/8/71

By late afternoon of April 8, the crowd in the administrative area on the second floor of the Hospital had increased to 80 to 100 persons and refused to disperse. They called for the personal appearance of Dr. Gonda. They occupied the entire administrative area making it necessary for the Hospital administrative staff to discontinue their work and to lock the offices. The doors on either end of the corridor were closed and people entering the administrative area were challenged as to their business. The locked administrative offices were broken into by removing a door from the hinges so that the entire complex of offices was occupied. Administrative personnel necessarily left the area and all the files, facilities, and resources of the administrative section including the emergency and disaster radio and special telephonic equipment were inaccessible for the use of the Hospital. The occupiers placed guards on the doors at each end of the administrative corridor. This corridor connects clinic and treatment facilities on one side with blood banking, laboratory and hospital wards on the other. Hospital personnel and patients were permitted to pass after identification through a corridor crowded with a large number of people. Certain personnel of the Medical Center were required by the occupying group to leave the administrative area while certain outside groups of individuals were allowed to come and go.

The Black Advisory Committee of Hospital employees met with the group occupying the premises and discussed their demands, chiefly the rehiring of Mr. Sam Bridges, at about 4 p.m. on April 8. After these discussions, the Black Advisory Committee issued a statement at about 5:00 p.m. stating that new information regarding Mr. Bridges had come to light in the discussions and that another meeting with the Black United Front would be held at 8:00 a.m. on the following morning, Friday, April 9.

It was hoped that arrangements for a meeting at 8:00 a.m. on the following morning would result in dispersal of the occupying group which, however, reiterated the demand that Dr. Gonda must meet with them in person before they would leave the administrative area. Therefore, at 7:00 p.m. on Thursday, April 8, Dr. John Wilson, Acting Dean of the Medical School and Executive Officer of the Medical Center, met for approximately an hour with the occupying group. They were informed that their action in taking

possession of the administrative area of the Hospital and inhibiting normal traffic between patient care areas constituted a disruption of Hospital function and was a threat to the welfare of the patients in the institution.

It was noted at that time that the group involved in the occupation consisted almost entirely of persons from outside the Medical Center and the University. A few Hospital employees were present. Discussions were conducted in a crowded, closed conference room by persons who did not identify themselves. It was not possible to learn who was the individual or individuals in charge of the occupation. It was now clear that complete control of the administrative section of the Hospital had been established. The demand for the presence of Dr. Gonda continued and it was agreed to call him to the administrative area in the hope of resolving the difficulties and terminating the occupation.

Dr. Gonda arrived about 10:00 p.m. and spent until midnight conferring with the group in an attempt to reach agreement on the demands and to terminate the occupation. Dr. Gonda reiterated an earlier assurance that the grievance procedure of the Hospital was still available to Mr. Bridges and that he would receive reinstatement and all back pay if the findings were in his favor. Agreement was reached with the Black United Front group on all of the demands except for the immediate rehiring of Mr. Sam Bridges. The group stated that they intended to occupy the premises until Mr. Sam Bridges was rehired. At 12:30 a.m. on Friday, April 9, it was obvious that a sit-in was intended. They were again urged to leave, were again strongly advised that their continued occupation was a disruption of Hospital function, and were told that it would be necessary for the University to seek legal advice on means to terminate the occupation.

At 8:00 a.m. on April 9, the Black Advisory Committee met with the sit-in group in the administrative suite and heard witnesses regarding the work performance of Mr. Bridges. The BAC then issued the following statement:

April 9, 1971

Hospital Employees

The Black Advisory Committee

Reinstatement of Sam Bridges

In a hearing held this morning by The Black Advisory Committee and The Black United Front, all of the charges made against Sam Bridges were reviewed. All available witnesses were confronted and their statements reanalyzed. The purpose of this hearing was to ascertain the true facts surrounding the dismissal of Mr. Bridges.

Due to new and pertinent facts brought out at this hearing, the Black Advisory Committee recommends that Sam Bridges be rehired and be retroactively reimbursed for total time loss.

The new and pertinent facts referred to in the above document were essentially a reversal by the witnesses of their original statements according to the Black Advisory Committee.

Doctor Gonda received the above recommendation from the Black Advisory Committee and agreed to submit it for review by an impartial referee acceptable to Mr. Bridges, the Black United Front and the University in accordance with the final stage of the grievance procedure of the Hospital. Mr. Henry Organ was acceptable as the referee to Mr. Bridges and the BUF. Doctor Gonda disqualified himself from the grievance procedure and agreed to recommend Mr. Organ to Acting President Miller. This was not acceptable as a solution to the sit-in group which, after 2 hours of discussion with Doctor Gonda, voted at 1:45 p.m. to sit-in until Mr. Bridges was rehired. Doctor Gonda did not agree with this demand and left the meeting.

Acting President Miller then wrote the following note which was delivered to the sit-in at about 4:30 p.m.

STANFORD UNIVERSITY

April 9, 1971

STATEMENT BY WILLIAM F. MILLER

Dr. Gonda has conveyed to me his recommendation for his replacement in the Grievance Procedure. I have that under consideration. However, we agree there will be no conclusion on the composition or dates for the Grievance Procedure while the occupation of the Hospital continues. Under existing circumstances, Dr. Gonda and I concur he should not return to the discussions.

[signed]
William F. Miller
Acting President

There was no response from the sit-in and no indication of any kind that the occupation would end. About 5:30 p.m. one of the sit-in members (Mr. Willie Newberry) is quoted by the Palo Alto Times as saying that they would occupy the premises until the Bridges' case was settled and that "they're going to have to restore the man."

After 30 hours of occupation and extensive but unsuccessful negotiations, it was considered necessary to invoke the trespass law and to call for its enforcement. The Palo Alto Police arrived at 5:45 p.m. and informed the sit-in that the occupation was unlawful. Many promptly left but more than 50 stayed, barricaded themselves in the administrative area where they completely destroyed the furniture and equipment. In removing the occupants of the area there were 23 arrests. Six of the occupants and 13 policemen were injured, none seriously. Property loss is estimated to be about $100,000.

The problem of rehiring of Mr. Bridges could have been readily solved by resort to the regular grievance procedures of the Hospital. These were made available to him and he was assured of back pay if his firing proved unjust. He and his BUF supporters chose instead to demand re-instatement and

attempted to achieve that demand by occupying the administrative area of the Hospital. The reason given for this course of action was racial discrimination in evaluation of Mr. Bridges' work performance. If true, the grievance procedure provides a constructive means of redress. On the other hand, the sit-in was a threat of force and created an atmosphere in which sound interpretation and judgment were exceptionally difficult or impossible. It seemed unwise to accept an imposed settlement when there was ready access to another more effective process such as the grievance procedure.

Patient care was threatened by the occupation of the administrative offices and adjacent major corridor. The effects of the sit-in were many and increased with time. Forced entry into administrative offices placed equipment, facilities, confidential files in jeopardy and made them inaccessible. Counselling services were interrupted. Administrative personnel were dispersed and lost efficiency or function. The time of many staff members and others was consumed in dealing with the occupation and its side effects. The occupation of the administrative area interfered with the normal flow of doctors, secretaries, and technologists between the surgical pathology suite and the tissue processing areas of the pathology department in the Lane building. In several instances, personnel attempting to pass through the corridor were stopped and harrassed by individuals who were sitting-in. Another problem concerned the blood bank ~~and the transfusion issue service, both of which are located in the west corrid~~or immediately adjacent to the administrative suite. Both of these vital areas had to be closed down because of the disruption and the functioning of the blood bank and the transfusion issue service was seriously inconvenienced by the inability to use the areas in which those functions are normally carried out. Heart transplant patients were denied access to physical therapy through fear of viral or bacterial contamination in the crowded administrative corridor. Passage of patients and hospital personnel was allowed through the guarded administrative corridor but the sight of dozens of people sitting on floor and desks created apprehension and frustration. Toilet, telephone and waiting room facilities adjacent to the administrative area were overloaded while patients, relatives and hospital personnel were dislocated, re-routed and inconvenienced. Certain informational, management and planning activities were disrupted. Personnel were required to be stationed at various hospital locations in order to route visitors and the curious away from the affected areas. The occupation created apprehension among some patients and families. One patient demanded to be released from the hospital and was. In summary, normal hospital functions were disturbed and its capability to respond to patient needs was reduced. Members of the occupying group demanded evidence that patients were actually being harmed before considering that the sit-in was detrimental to patient care. It is unacceptable to allow conditions to deteriorate to this point.

Decision to invoke the trespass law was made only after hours of consultation and review of alternatives. There was no indication that the sit-in would be ended except by the rehiring of Mr. Bridges. That did not seem appropriate under the circumstances. The prospects were that the sit-in would become progressively better organized and entrenched. I recommended that the law enforcement officers of Palo Alto be requested to terminate the sit-in at 6:00 p.m. on April 9. Acting President Miller concurred fully and the necessary steps were taken. It is hoped that the unfortunate consequences of this event will not obscure the path to better understanding of our society and of the methods which we may safely use to effect the long-needed changes in it.

STANFORD -- Two members of the Black Advisory Committee and the director of Latin Resources at Stanford University Hospital said Monday demonstrators were making plans to end their sit-in at the hospital when police were called.

Mrs. Nadine Ellis and Mrs. Lovie Lewis of the BAC said protesters were ready to leave the building as soon as they got word from Hospital Director Thomas A. Gonda that a grievance procedure for Sam Bridges had been set up.

The demonstrators had staged the sit-in in the hospital's administrative offices to protest the firing of Bridges, a Black employee. The 30-hour occupation was ended last Friday by Palo Alto police, and there was an estimated $100,000 damage which Mrs. Ellis feels would have been avoided.

According to Mrs. Ellis, BAC chairman Jim Cheatham had talked with Black United Front leaders and it was agreed that "if word came that Bridges was going through a grievance procedure, and Henry Organ were the mediator, the protestors would leave at 6 p.m. (Friday, April 9)."

Henry P. Organ of East Palo Alto, is an associate general secretary at Stanford and a respected Black leader.

Tony Rodriguez of the Latin Alliance said he visited the occupied offices as an observer at 5:15 p.m. Friday and he, too, was told the BUF was "shooting for a six o'clock evacuation of the premises."

"I observed the area to be in a high state of cleanliness and order," said Rodriguez. "Even ash trays were being cleaned. The BUF was determined to avoid the usual charge of vandalism."

The three minority group members told the Stanford Medical Center News Bureau they were making the statement because they felt the News Bureau and press accounts of the demonstration had emphasized only Stanford's reasons for the police action, and had obscured other important aspects of the protest.

Press accounts, they said, did not mention that among the demonstrators protesting the firing of Sam Bridges were fellow employees at the hospital, and not all protesters were radicals from the outside.

"We want to make the point that many hospital employees were trapped in the demonstration, and some were injured as they tried to escape," said Mrs. Ellis who, with other BAC members, was still trying to negotiate a peaceful settlement with Bridges' supporters.

She and the other BAC members barely got out of the occupied offices as police arrived, Mrs. Ellis said. She was especially concerned, she said, about possible injury to herself because she is expecting a baby.

Attached is a memorandum of April 12 from John L. Wilson, M.D., acting dean of the School of Medicine, to the faculty, staff and students of the Medical School. Dr. Wilson gives in some detail the sequence of events at Stanford University Hospital, beginning with the first rally of the Black United Front Tuesday, April 6, through the forcible evacuation of demonstrators from the administrative offices the evening of Friday, April 9.

The critical timing of the exchange of messages among the sit-in group, the Medical School administration, and the University administration is reviewed.

"Patient care was threatened by the occupation of the administrative offices and adjacent major corridor," Dr. Wilson stated. "The effects of the sit-in were many and increased with time. . . . Members of the occupying group demanded evidence that patients were actually being harmed before considering that the sit-in was detrimental to patient care. It is unacceptable to allow conditions to deteriorate to this point.

"Decision to invoke the trespass law was made only after hours of consultation and review of alternatives. There was no indication that the sit-in would be ended except by the rehiring of Mr. Bridges. That did not seem appropriate under the circumstances. The prospects were that the sit-in would become progressively better organized and entrenched.

"I recommended that the law enforcement officers of Palo Alto be requested to terminate the sit-in at 6 p.m. on April 9. Acting President Miller concurred fully and the necessary steps were taken."

Dean Wilson makes this evaluation:

"The problem of rehiring of Mr. Bridges could have been readily solved by resort to the regular grievance procedures of the Hospital. These were made available to him and he was assured of back pay if his firing proved unjust. He and his BUF supporters chose instead to demand reinstatement and attempted to achieve that demand by occupying the administrative area of the Hospital. The reason given for this action was racial discrimination in evaluation of Mr. Bridges' work performance. If true, the grievance procedure provides a constructive means of redress.

"On the other hand, the sit-in was a threat of force and created an atmosphere in which sound interpretation and judgment were exceptionally difficult or impossible. It seemed unwise to accept an imposed settlement when there was ready access to another more effective process such as the grievance procedure."

4/13/71

April 12, 1971

TO: Medical Staff and Students

FROM: John L. Wilson, M.D.
Acting Dean, School of Medicine

SUBJECT: Sit-in at the Stanford University Hospital on April 8-9, 1971

On Tuesday, April 6, a noon rally was held on the lawn near the Medical Center by the Black United Front. The BUF is said to be a coalition of the Black Liberation Front, the Black Workers Caucus and representation from the Black Student Union. The Front was organized as a response to the dismissal of Mr. Sam Bridges, a hospital employee, and the laying off of workers at Tresidder. Following the rally on April 6, over 100 persons went to the office of Doctor Gonda, Director of the Hospital, and presented to him a list of 6 demands. They stated that they would return for a reply to these demands at noon on Thursday, April 8. As far as is known, the groups presenting the demands included few if any Hospital employees.

On April 9, another noon rally was held following which about 50 persons went to the office of Doctor Gonda stating that they expected to receive from him, in person, the reply to their demands. The reply had been printed in the Daily on that morning and copies of it were handed to the group. The demands, with Dr. Gonda's responses to them, are printed below:

1. "Workers must have the right to criticize administration policies from the date of hiring without intimidation."

   All employees have the right to criticize administration policies. In addition, there are regular opportunities of communicating employee views to the administration. If there are any instances in which that policy has been violated, I would appreciate having the evidence brought to my attention.

2. "Workers must have the right to organize a union which represents the workers' interest."

   Employees are free to decide if they wish to join unions. The Hospital was involved in a union election in 1967, and union organizing activities have been held regularly since then.

3. "Workers must have grievance rights from date of hiring."

   Present Hospital policy is ambiguous on this point. Our practice, however, has been to make grievance procedures available to employees regardless of length of service. I will take steps to clarify the Policy Manual on this point.

4. "Workers must have the right to have peers present on all grievance procedures."

   While the grievance procedure does not explicitly provide for the presence of peers at the early steps, our practice has been to allow it as is expressly set forth in later steps of the grievance procedure.

4) He was counselled about his work performance on at least three different occasions due to complaints by his co-workers.

5) He was observed on campus several times while he was supposed to be working.

The Black Advisory Committee can present evidence to substantiate these facts. It was our conclusion that Mr. Bridges was terminated because he was not doing the job he was hired to do, and therefore putting an added burden on his co-workers.

Had Mr. Bridges, after being told about the grievance procedure, chosen to take his case before the grievance committee, this Committee would have insured him fair and impartial treatment.

4/8/71

By late afternoon of April 8, the crowd in the administrative area on the second floor of the Hospital had increased to 80 to 100 persons and refused to disperse. They called for the personal appearance of Dr. Gonda. They occupied the entire administrative area making it necessary for the Hospital administrative staff to discontinue their work and to lock the offices. The doors on either end of the corridor were closed and people entering the administrative area were challenged as to their business. The locked administrative offices were broken into by removing a door from the hinges so that the entire complex of offices was occupied. Administrative personnel necessarily left the area and all the files, facilities, and resources of the administrative section including the emergency and disaster radio and special telephonic equipment were inaccessible for the use of the Hospital. The occupiers placed guards on the doors at each end of the administrative corridor. This corridor connects clinic and treatment facilities on one side with blood banking, laboratory and hospital wards on the other. Hospital personnel and patients were permitted to pass after identification through a corridor crowded with a large number of people. Certain personnel of the Medical Center were required by the occupying group to leave the administrative area while certain outside groups of individuals were allowed to come and go.

The Black Advisory Committee of Hospital employees met with the group occupying the premises and discussed their demands, chiefly the rehiring of Mr. Sam Bridges, at about 4 p.m. on April 8. After these discussions, the Black Advisory Committee issued a statement at about 5:00 p.m. stating that new information regarding Mr. Bridges had come to light in the discussions and that another meeting with the Black United Front would be held at 8:00 a.m. on the following morning, Friday, April 9.

It was hoped that arrangements for a meeting at 8:00 a.m. on the following morning would result in dispersal of the occupying group which, however, reiterated the demand that Dr. Gonda must meet with them in person before they would leave the administrative area. Therefore, at 7:00 p.m. on Thursday, April 8, Dr. John Wilson, Acting Dean of the Medical School and Executive Officer of the Medical Center, met for approximately an hour with the occupying group. They were informed that their action in taking

Doctor Gonda received the above recommendation from the Black Advisory Committee and agreed to submit it for review by an impartial referee acceptable to Mr. Bridges, the Black United Front and the University in accordance with the final stage of the grievance procedure of the Hospital. Mr. Henry Organ was acceptable as the referee to Mr. Bridges and the BUF. Doctor Gonda disqualified himself from the grievance procedure and agreed to recommend Mr. Organ to Acting President Miller. This was not acceptable as a solution to the sit-in group which, after 2 hours of discussion with Doctor Gonda, voted at 1:45 p.m. to sit-in until Mr. Bridges was rehired. Doctor Gonda did not agree with this demand and left the meeting.

Acting President Miller then wrote the following note which was delivered to the sit-in at about 4:30 p.m.

STANFORD UNIVERSITY

April 9, 1971

STATEMENT BY WILLIAM F. MILLER

Dr. Gonda has conveyed to me his recommendation for his replacement in the Grievance Procedure. I have that under consideration. However, we agree there will be no conclusion on the composition or dates for the Grievance Procedure while the occupation of the Hospital continues. Under existing circumstances, Dr. Gonda and I concur he should not return to the discussions.

[signed]
William F. Miller
Acting President

There was no response from the sit-in and no indication of any kind that the occupation would end. About 5:30 p.m. one of the sit-in members (Mr. Willie Newberry) is quoted by the Palo Alto Times as saying that they would occupy the premises until the Bridges' case was settled and that "they're going to have to restore the man."

After 30 hours of occupation and extensive but unsuccessful negotiations, it was considered necessary to invoke the trespass law and to call for its enforcement. The Palo Alto Police arrived at 5:45 p.m. and informed the sit-in that the occupation was unlawful. Many promptly left but more than 50 stayed, barricaded themselves in the administrative area where they completely destroyed the furniture and equipment. In removing the occupants of the area there were 23 arrests. Six of the occupants and 13 policemen were injured, none seriously. Property loss is estimated to be about $100,000.

The problem of rehiring of Mr. Bridges could have been readily solved by resort to the regular grievance procedures of the Hospital. These were made available to him and he was assured of back pay if his firing proved unjust. He and his BUF supporters chose instead to demand re-instatement and

HEART TRANSPLANT #13 Dead 4-13-71

STANFORD -- James E. Pounds, a heart transplant patient at Stanford, died this morning at Stanford University Hospital. The 60-year-old patient lived exactly two years to the day after his transplant operation April 13, 1969.

He is survived by his wife Louise, and their sons James and Ronald, who is stationed at McGuire Air Force Base, New Jersey. The family moved to Palo Alto in 1969 after the transplant operation. Their hometown is Bakersfield, California, where Pounds had been employed with an oil company.

Of Stanford's 30 heart transplant patients, there are now 11 survivors.

FOR IMMEDIATE RELEASE

STANFORD –

Some 400 persons attended an orderly morning rally at the Stanford Medical School today and voiced support for the black students and workers who are protesting the firing of hospital worker Sam Bridges.

Several senior members of the Medical School faculty spoke out in support of the blacks, including Dr. William C. Dement, Dr. Avram Goldstein, and Dr. Halsted R. Holman.

Dr. Adayapalam T. Ganesan, who moderated the rally, announced two resolutions of a faculty coalition group, which was formed Saturday night under the leadership of Holman. The coalition group condemned the action of calling police to evacuate demonstrators at the Medical Center Friday night and gave support to the blacks and Latin Americans against the "racism" at Stanford, Ganesan said.

None of the faculty members at today's rally specifically commented on the eight "nonnegotiable" demands issued yesterday by the Black Advisory Committee in conjunction with students in the Stanford School of Medicine. Indirectly, however, they seemed to be supporting the BAC demand that "the decision-making apparatus must exist only with horizontal authority. This restructuring is imperative."

Holman called for a "new system" which would result in all employees at the Medical Center and hospital working together "to criticize and improve all aspects of the medical program."

Goldstein charged that the police action of Friday night was "part of the repression that's gone on here at this campus, and part of the repression of blacks and Latin Americans that goes on every day and has gone on every day for hundreds of years. Nobody has to call in police to smash up our people, our furniture and our hospital. . . . After an action like this, I don't see how Wilson [Acting Dean John L.] can command the respect necessary to be the dean of an institution like this."

Goldstein also called for a "restructuring of the way this institution is run. This means rooting out the elitism we have here and transforming it in some effective way into a more democratic institution."

Dement, claiming that "racism hasn't been eradicated at Stanford," called for all whites on campus to convince the blacks that they have nothing to fear at Stanford.

"The black student walks in fear," Dement said. "He knows that when there is trouble, he'll be singled out by police." When a black worker is fired or a black applicant rejected, we can't be sure it is not because of his color, he added.

Dement also stressed that whites have nothing to fear from blacks at Stanford.

"We are afraid of what blacks will do, afraid of what they will ask, afraid we will lose too much," Dement said. "We whites really have nothing to fear. I trust the blacks at Stanford, and feel they want to make it a better place. Furthermore, I feel that Stanford is a better place because of the blacks here already. . . . I have not read the demands, but I support the blacks without qualification."

Sam Bridges made a brief appearance at the rally.

Shortly afterward about 75 people from the rally went to the President's Office in the Inner Quad and said they wanted to ask questions of Provost William F. Miller. They left after being told he was not there.

Following a noon rally in White Plaza, attended by about 250 persons, a small group of chicano students demonstrated in front of the President's Office Tuesday afternoon, demanding that Dr. Jose Aguilar of the Medical School be given tenure.

They were advised that both President Richard W. Lyman and Provost Miller were not available to discuss the matter. President Lyman was in San Francisco at the Board of Trustees meeting. Provost Miller was at the Medical Center.

(Dr. Wilson described as "unfounded" charges that Dr. Aguilar, assistant professor of neurosurgery since 1965, was denied tenure on racial grounds.)

The chicano students were part of a rally which attended the opening of Semana Latina on campus, a week-long series of skits and music depicting Mexican-American culture.

A scheduled noon rally called by the Black United Front in White Plaza was preempted by the chicano program. The black group had called the rally in protest of alleged police brutality at the Medical School sit-in Friday afternoon.

A group of 23 black students served themselves in the cafeteria line at Tresidder Union shortly after 1 p.m., carried the trays outside without paying for the food, and afterward dumped trays and dishes in the waste bins outside, Tresidder officials reported.

STANFORD -- James Gary Bowerman, a fifth-year student at Stanford University School of Medicine, is this year's Stanford recipient of the Pfizer Laboratories Medical Scholarship.

The scholarship, in the amount of $1000, was awarded on the basis of Bowerman's outstanding scholastic record. He has been commended on several occasions for excellent performance in medical school and was elected to the Stanford chapter of Alpha Omega Alpha, the national medical honor society, in December 1970.

The son of Mr. and Mrs. Harold L. Bowerman of Leaf River, Illinois, he plans to take his internship training in pediatrics. The internship begins July 1 at Bernalillo County Medical Center, Albuquerque, New Mexico.

Pfizer Laboratories makes scholarship awards at all the medical schools in the United States.

Mailed April 14, 1971.

STANFORD -- At a special meeting Wednesday morning, the Faculty Senate of the Stanford School of Medicine unanimously pledged their support to "constructive efforts to resolve our present difficulties" and said all constituencies of the Medical Center should join together "to work toward equitable solutions under the continuing leadership of Dr. John L. Wilson."

Of the 29 Senate members present on campus, 23 attended the meeting. The Senate has 36 members.

The Senate resolution urged "the prompt review of current policies and adoption, if not already available, of effective, impartial, formal procedures for the resolution of current and future grievances."

"We reaffirm that the University policy on campus disruption applies to the Stanford Medical School and Hospital as an integral part of the University community," the Senate said.

"As physicians and teachers of medicine whose concern is the care of patients, and as individuals who wish to preserve the opportunity for peaceful expressions of dissent, we endorse the view that the use of force and threats of force cannot be tolerated in any hospital," the Senate said.

Text of the Senate resolution follows: "The Faculty Senate of the Stanford University School of Medicine expresses deep concern when circumstances exist wherein grievances of Hospital and Medical School workers are not peaceably resolved. It is tragic when an unresolved conflict results in violent confrontation, and we deplore the fact that recent events escalated beyond control of the internal Stanford community and resulted in the use of police force.

"We reaffirm that the University Policy on Campus Disruption applies to the Stanford Medical School and Hospital as an integral part of the University community. As physicians and teachers of medicine whose concern is the care of patients, and as individuals who wish to preserve the opportunity for peaceful expressions of dissent, we endorse the view that the use of force and threats of force can not be tolerated in any hospital.

"We urge the prompt review of current policies and the adoption if not already available, of effective, impartial formal procedures for the resolution of current and future grievances.

"We pledge ourselves to the support of constructive efforts to resolve our present difficulties and urge all the constituents of the Medical Center to join together to work toward equitable solutions under the continuing leadership of Dr. John L. Wilson."

Dr. Merton R. Bernfield, Senate chairman, said the special meeting was called to discuss recent events at the Medical Center and to designate a Senate representative to serve on the dean ad hoc committee on the Center's current problems.

Every Senate member available was contacted prior to the meeting. Those attending were: Robert S. Turner (Anatomy); Grant Fletcher (Anesthesia); David S. Hogness (Biochemistry); Byron W. Brown (Community & Preventive Medicine); Alvin J. Cox (Dermatology); Elliott C. Levinthal (Genetics); Leonard Hayflick (Medical Microbiology); Robert J. Roantree (Medical Microbiology); Allen B. Barbour (Medicine); Kao L. Chow (Neurology); Mary Herman (Pathology); David Korn (Pathology); Merton R. Bernfield (Pediatrics); Wm. van B. Robertson (Pediatrics); Sumner M. Kalman (Pharmacology); Ronald Grant (Physiology); George D. Gulevich (Psychiatry); P. Herbert Leiderman (Psychiatry); Norman Blank (Radiology); Robert F. Kallman (Radiology); William H. Northway, Jr. (Radiology); Lawrence G. Crowley (Surgery); James B. D. Mark (Surgery). ###

STANFORD -- Hospital officials have again affirmed, in writing, their willingness to assure prompt grievance procedures, on request, for Sam Bridges, the Black employee whose dismissal was cited as the reason for last week's demonstration at the Stanford Medical Center.

In a letter sent to Bridges Wednesday morning, Hospital Personnel Director Kenneth Dunkle reaffirmed the hospital's offer to waive the initial steps in the procedure, if requested. Dunkle said Hospital Director Thomas Gonda had agreed to have Henry Organ of the General Secretary's Office serve as hearing officer for the final stage of the case.

On Friday afternoon, Dr. Gonda asked not to serve as the hearing officer. While discussions had indicated that Organ was mutually regarded as an acceptable replacement, University officials said they would not reach a conclusion on the composition or dates for the procedure until the hospital occupation ended.

If Bridges requests that the initial steps of the grievance procedure be waived, Dunkle said, he would have a "full opportunity to present any facts and arguments" in an informal hearing with Organ, whose decision would be final.

Bridges also would be welcome to have an individual of his own choice assist him in the hearing. In accord with hospital policy, Bridges also would be entitled to have two hospital employees of his choice attend the hearing.

A copy of the letter was sent to James Cheatham of the Black Advisory Committe, a hospital employee group, and to Organ.

Dunkle wrote Bridges that if he wished to request a grievance procedure, he should do so no later than 5 p.m. Wednesday, April 21, one week hence.

Employees may present their grievance initially to their immediate supervisors, and then to the department head and the associate director for personnel. At the third stage, the employee may select two of his co-workers to attend a conference with his department head, line administrator, and the associate director for personnel.

Bridges, who was dismissed March 19 after several weeks' employment, has not yet requested a grievance procedure.

The BAC and other groups have demanded his reinstatement.

FOR IMMEDIATE RELEASE

STANFORD –

Ten chicano faculty, administrators, and staff members at Stanford have called for re-examination of the "arbitrary" decision not to grant tenure to Assistant Prof. Jose Aguilar, neurosurgeon at the Medical School.

In a statement published in *The Stanford Daily* Wednesday, April 14, they said: "The University's attitudes and actions in this case have not been in keeping with its commitment to the chicano community on campus and to a strong affirmative action program.

"We are not asking that Dr. Aguilar be kept on because he is a chicano; we believe that all faculty should be judged on their competence and performance. The implications of not rehiring Dr. Aguilar go beyond his individual case and affect the entire chicano community."

Objecting to the manner in which the entire case has been handled, they contended there have been "irregularities" in the initial decision and subsequent reviews: "(1) Dr. Aguilar was not given documented reasons for his dismissal after having requested them.

(2) At an open meeting on April 5, members of the Department of Surgery [four deans and one department chairman] who partook in the original decision admitted that they did not feel competent to judge Dr. Aguilar's work; they, therefore, voted on the basis of the chairman of the neurosurgery division's opinion in this matter.

(3) Obstacles in the way of Dr. Aguilar's fulfillment of his obligation for tenure have not been taken into account."

Signers of the statement included: Carlos Jackson, assistant dean, Dean of Student Office; Lorenzo A. Esquibel, staff associate, SLAC; Ray Caldera, personnel representative, Personnel Services Department; Maria Baeza, assistant to the dean of the Graduate Division; Maria Gutierrez, financial aids counselor; Jose I. Santos, technical assistant, Department of Biological Sciences; Gil Chavez, assistant director of admissions; Renato Rosaldo, assistant professor, Anthropology Department; Arturo Islas, acting assistant professor, English Department; and Lilia Garfinkle.

MECHA, the chicano student organization at Stanford, presented a petition on Dr. Aguilar's behalf at the President's Office Tuesday, and the Student Senate passed a resolution calling for his rehiring with tenure.

Dr. John L. Wilson, acting dean of the Medical School, last week called reports that Dr. Aguilar was denied tenure on racial grounds "unfounded."

According to faculty appointment procedures of the Medical School, Dr. Aguilar was notified in November 1970 that he would not be reappointed, Dr. Wilson explained.

The decision was made by an eight-member committee of the senior faculty of the Department of Surgery.

Dr. Aguilar's case was reviewed again in March 1971, at his request, and the decision not to reappoint him was upheld, Dr. Wilson said.

Dr. Wilson said that Dr. Aguilar is not the only assistant professor who did not get a reappointment. Funding problems, research projects that do not pan out, faculty productivity, or changing departmental needs count heavily in the reappointment of faculty, he commented.

4/14/71

FOR IMMEDIATE RELEASE

STANFORD - Provost William F. Miller of Stanford Wednesday afternoon, April 14, ~~xxx~~ received a list of 11 demands from a newly formed Stanford Employees Coalition calling for reinstatement of Sam Bridges, dropping of all legal charges, and payment of legal and medical expenses for those involved in last week's occupation of the hospital.

James Cheatham of the Black Advisory Committee gave the demand to Provost Miller (on the lawn outside the Medical School) and set a 9 a.m. Monday deadline for a reply. Tony Rodriguez of the Latin Alliance and Willie Newberry of the Black Students Union were present when ~~xxx~~ Miller read the demands over a microphone, said "we will be getting people together to start ~~xxxxxx~~ these discussions," shook hands with Cheatham and left.

Other demands included having Dr. John L. Wilson resign as acting dean of the Medical School, granting tenure to Dr. Jose Aguilar, sole chicano on the Medical School faculty, and having ~~xxxxxxxxxxxxxxx~~ a black and Latin committee empowered to "evaluate the policies, practices and procedures" of all departments in the Medical Center, including development of an affirmative action program and evaluation of the Personnel Department.

Further demands having Stanford employee medical coverage include spouses, clear job descriptions and salaries, having four black and Latin delegates added to the Administrative Council of the hospital, and providing up to six months leave time for "acceptable and legitimate" reasons without job loss.

~~Xhxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx~~ Besides Dr. Wilson, the employee group called for having Deputy Hospital Director Frank Vitale and Warren Thorp e, assistant chief of engineering ~~and~~ (and Bridges supervisor) relieved of all Medical Center duties, with a black and Latin committee approving their replacements.

Provost Miller asked Cheatham and others present to designate the individuals from their group who would participate in the discussions.

#####

The following list of demands was presented by James Cheatham of the Black Advisory Committee to Stanford Provost William F. Miller at 1:35 p.m. Wednesday, April 14, following a rally on the lawn near the Medical School. A deadline of 9 a.m. Monday was set for a response. Tony Rodriguez of the Latin Alliance and Willie Newberry, co-chairman of the Black Students Union, were present when the demands were read by Provost Miller to a crowd of about 100. Miller said "we will be getting people together to start these discussions" and asked Cheatham and others present to indicate as soon as possible whom they would designate to participate in these discussions (Med.Center News Bureau)

THAT STANFORD EMPLOYEES COALITION DEMANDS OF THE ADMINISTRATION THAT:

1. ALL CHARGES RELATED TO ALL PERSONS WHO WERE ARRESTED IN CONNECTION WITH THE DEMONSTRATION HELD AT THE STANFORD UNIVERSITY HOSPITAL APRIL 9, 1971 BE DROPPED. NOTWITHSTANDING, ALL LEGAL FEES INCURRED DURING THIS DEMONSTRATION SHALL BE PAID IN FULL BY STANFORD UNIVERSITY.

2. ANY PERSONS WHO RECEIVED ANY FORM OF INJURY BECAUSE OF THEIR DIRECT OR INDIRECT INVOLVEMENT IN THE DEMONSTRATION SHOULD HAVE ALLMEDICAL EXPENSES PAID IN FULL BY STANFORD UNIVERSITY.

3. SAM BRIDGES SHALL BE REINSTATED AND REIMBURSED RETROACTIVELY FROM DATE OF TERMINATION.

4. THE FOLLOWING:

   a) Dr. John L. Wilson resign as Acting Dean

   b) Frank Vitale, Deputy Director of the Hospital, be relieved of all Medical Center duties.

   c) Warren Thorpe, Assistant Chief of Engineering, be relieved of all Medical Center duties.

   d) Black and Latin Committee must approve those persons hired as replacements in a, b, and c as well as the now vacant Chief Engineer position.

5. DR. JOSE AGUILAR BE GRANTED TENURE.

6. THE BLACK AND LATIN COMMITTEE BE EMPOWERED TO INVESTIGATE AND EVALUATE POLICIES, PRACTICES AND PROCEDURES OF ALL DEPARTMENTS IN THE MEDICAL CENTER. THE FIRST PRIORITIES OF THE COMMITTEE SHALL BE:

   a) The development and implementation of the Affirmative Action Program and

   b) Evaluation of the Personnel Department.

7. THAT FOUR (4) VOTING PLACES BE FILLED BY BLACK AND LATIN DELEGATES ADDED TO THE ADMINISTRATIVE COUNCIL OF THE HOSPITAL.

8. ANY EMPLOYEE WHO HAS TO TAKE A LEAVEFOR AN ACCEPTABLE AND LEGITIMATE REASON, SHOULD HAVE THE RIGHT TO DO SO. STARTING WITH THE FIRST DAY OF LEAVE, HE SHOULD BE GRANTED LEAVE TIME UP TO SIX MONTHS. THE JOB SHOULD BE LEFT OPEN FOR THE EMPLOYEE WHEN LEAVE IS TERMINATED. THIS AGREEMENT SHALL BE REDUCED SUCCINCTLY TO WRITING.

9. HOUSEKEEPING ASSISTANTS SHOULD BE AT LIBERTY TO USE ANY RESTROOM DESIGNATED FOR STANFORD HOSPITAL EMPLOYEES.

10. STANFORD'S EMPLOYEE'S MEDICAL COVERAGE SHOULD ALSO INCLUDE COVERAGE FOR THE EMPLOYEE'S SPOUSE.

11) EACH JOB SHOULD BE CLEARLY CLASSIFIED, AS WELL AS, DESCRIBED. FURTHER, EACH JOB SALARY SHOULD BE STATED IN WRITING.

The following list of demands was presented by James Cheatham of the Black Advisory Committee to Stanford Provost William F. Miller at 1:35 p.m. Wednesday, April 14, following a rally on the lawn near the Medical School. A deadline of 9 a.m. Monday was set for a response. Tony Rodriguez of the Latin Alliance and Willie Newberry, co-chairman of the Black Students Union, were present when the demands were read by Provost Miller to a crowd of about 100. Miller said "we will be getting people together to start these discussions" and asked Cheatham and others present to indicate as soon as possible whom they would designate to participate in these discussions (Med.Center News Bureau)

3. SAM BRIDGES SHALL BE REINSTATED AND REIMBURSED RETROACTIVELY FROM DATE OF TERMINATION.

4. THE FOLLOWING:

   a) Dr. John L. Wilson resign as Acting Dean

   b) Frank Vitale, Deputy Director of the Hospital, be relieved of all Medical Center duties.

   c) Warren Thorpe, Assistant Chief of Engineering, be relieved of all Medical Center duties.

   d) Black and Latin Committee must approve those persons hired as replacements in a, b, and c as well as the now vacant Chief Engineer position.

5. DR. JOSE AGUILAR BE GRANTED TENURE.

6. THE BLACK AND LATIN COMMITTEE BE EMPOWERED TO INVESTIGATE AND EVALUATE POLICIES, PRACTICES AND PROCEDURES OF ALL DEPARTMENTS IN THE MEDICAL CENTER. THE FIRST PRIORITIES OF THE COMMITTEE SHALL BE:

   a) The development and implementation of the Affirmative Action Program and

   b) Evaluation of the Personnel Department.

7. THAT FOUR (4) VOTING PLACES BE FILLED BY BLACK AND LATIN DELEGATES ADDED TO THE ADMINISTRATIVE COUNCIL OF THE HOSPITAL.

8. ANY EMPLOYEE WHO HAS TO TAKE A LEAVEFOR AN ACCEPTABLE AND LEGITIMATE REASON, SHOULD HAVE THE RIGHT TO DO SO. STARTING WITH THE FIRST DAY OF LEAVE, HE SHOULD BE GRANTED LEAVE TIME UP TO SIX MONTHS. THE JOB SHOULD BE LEFT OPEN FOR THE EMPLOYEE WHEN LEAVE IS TERMINATED. THIS AGREEMENT SHALL BE REDUCED SUCCINCTLY TO WRITING.

9. HOUSEKEEPING ASSISTANTS SHOULD BE AT LIBERTY TO USE ANY RESTROOM DESIGNATED FOR STANFORD HOSPITAL EMPLOYEES.

10. STANFORD'S EMPLOYEE'S MEDICAL COVERAGE SHOULD ALSO INCLUDE COVERAGE FOR THE EMPLOYEE'S SPOUSE.

11) EACH JOB SHOULD BE CLEARLY CLASSIFIED, AS WELL AS, DESCRIBED. FURTHER, EACH JOB SALARY SHOULD BE STATED IN WRITING.

STATEMENT BY PRESIDENT RICHARD W. LYMAN
TO THE FACULTY SENATE

April 15, 1971

The last four sit-ins at Stanford have ended only when University officials asked the police to clear the area being occupied. I have said before, and I repeat now, that every time it is necessary to use the police at Stanford, a defeat is suffered. The defeat is not tactical or political; it consists of a blow to the conception of the University as a place of reason, not force. What follows, then, is not a "battle-plan", but a statement of policy that derives from that very idea of the University and the way in which it must conduct its affairs.

After each incident two themes were prominent in the arguments against the University's action. The first is that it was clear that the University would no longer allow peaceful sit-ins; the second is that everybody involved in the sit-in was surprised by the University's decision to call the police. I do not cite these two lines of argument in order to demonstrate their inconsistency, although they do appear inconsistent. Rather, I wish to take them as evidence of a continuing confusion over the way in which the Stanford administration views the use of the sit-in as a tactic. The importance of the question is obvious. It is not in anyone's interest to have people engage in an activity under a false set of expectations about the results to which that activity may lead. Therefore, I think it is worth an effort by me to bring as much clarity as I can to a set of policies which are inevitably shaped differently by the very circumstances of each case in which they must be applied.

Let me start, then, with the premise from which all else follows: Occupying a University building is not an acceptable form of political action within the University. When a sit-in occurs, it will be brought to an end as soon as possible, using the best judgment as to methods and timing that can be brought to bear on the circumstances of the particular case. This is quite similar to policies in existence at some other major universities, for example Yale and Princeton. Because that premise has guided University policy since the Encina Hall sit-in of 1969, we have experience to give content to the bare-bones statement of policy. It is worth looking at that experience.

The Encina sit-in produced a virtually immediate call for police assistance. In that case, the building was broken into late at night and once in, the people involved wandered throughout the building, searching desks and files and removing records. Encina Hall contains records vital to the functioning of the University. The imminent threat to those records could not be tolerated, hence the decision to call the police.

In the Spring of 1970, there were two sit-ins at the Old Union. On both occasions the occupation began during the day and the demonstrators were given what amounted to a set of ground rules. These were in essence that they were required to leave the building at 5 P.M., the close of business, and that in the meantime they had to conduct themselves in a way that did not disrupt the ordinary operations in the building. In both cases the group sitting in contained substantial numbers of people not associated with the University. For that and other reasons the decision was made that occupation of the building beyond the close of business constituted a serious threat to admissions, financial, and other records, and could not be allowed. In both cases, the group failed to leave when told to do so and the police were then called.

FOR IMMEDIATE RELEASE

STANFORD - Noting that last week's hospital demonstration was started "largely by outsiders, including a fair number of white radicals not connected with the University," President Richard W. Lyman of Stanford said Thursday, April 15, it would be "tragedy piled on tragedy" for the University to falter now in its commitments to "deal with the results of a long history of discrimination against ethnic minorities," including both blacks and chicanos.

Reviewing the incident with the faculty Senate for more than two hours at its regular session, the President made these points:

* "Occupying a building is not an acceptable form of political action within the University. When a sit-in occurs, it will be brought to an end as soon as possible, using the best judgment as to methods and timing that can be brought to bear on the circumstances of the particular case."

* Campus judicial proceedings may be initiated against the "very few" students involved, although arrests alone will not warrant prosecution. "Inquiries have been set in motion" about faculty and staff participation and arrests. (A majority of those arrested had no University affiliation; five were students, one was faculty, and five were staff members, including one hospital employee.)

* The University "has not conclusively resolved" whether to initiate civil damage suits against the demonstrators to recover an estimated $100,000 in property damages, as well as other losses. Asking for faculty opinion, Lyman added: "We can't continue to absorb losses on this scale" simply by deploring them.

* He said he is "hopeful" it will be possible to convert all or part of the campus police to regular peace officers. While no campus in the country has enough police of its own to deal with major disorders, "a genuine police force of our own would have many advantages," especially in dealing with conventional crime problems on campus.

In his opening remarks to the Senate, President Lyman said: "Every time it is necessary to use the police at Stanford, a defeat is suffered. The defeat is not tactical or political; it consists of a blow to the conception of the University as a place of reason, not force....

"I have no doubt at all that a very large majority of students, faculty, and staff at Stanford recognize that every sit-in is intended as an act of coercion, based on either force or the threat of force.

"This is true regardless of the composition of the group. (In three previous sit-ins where police were summoned) virtually all of the people involved were white; in the fourth case, there was a sizeable minority of blacks and a small number of chicanos.'

"This difference must not be a deterrent to the application of our policy. Any other conclusion would surely---and rightly---be condemned as a patronizing and insulting kind of discrimination on the basis of race or ethnic background."

(Among 23 arrested last week, there were 15 whites, five blacks, and three chicanos.)

FOR IMMEDIATE RELEASE

STANFORD -- Sam Bridges, the Black employee whose dismissal has been cited as the reason for last week's demonstration at the Stanford University Hospital, has agreed to submit his case to a grievance procedure.

Bridges requested the hearing Thursday (April 15), according to Personnel Director Kenneth Dunkle. Bridges, who was dismissed March 19 after several weeks of employment, had not previously requested a grievance procedure.

In a letter sent to Bridges Wednesday morning, Hospital officials affirmed their willingness to assure prompt grievance procedures, on his request.

Dunkle wrote that Hospital Director Thomas A. Gonda had agreed to have Henry Organ of the General Secretary's Office serve as the hearing officer for the final stage of the case. The Hospital offered to waive the initial steps of the procedure.

Arrangements for the hearing are being made, Dunkle said.

Meanwhile, Acting Dean John L. Wilson Thursday held informational sessions with associate deans, faculty representatives, and University officials to determine the manner in which discussions will be carried out with the newly formed Minority Advisory Committee.

The Committee Wednesday presented 11 demands calling for reinstatement of Bridges, dropping of all legal charges, and payment of legal and medical expenses for those involved in last week's demonstration at the Hospital. Other demands included having Dr. Wilson resign, granting tenure to Dr. Jose Aguilar, sole Chicano on the Medical School faculty, and having a Black and Latin committee empowered to evaluate the policies, practices, and procedures of all departments in the Medical Center.

SUNDAY, APRIL 18, 1971

TO: ALL DEPARTMENT HEADS

FROM: THOMAS A. GONDA, M.D., DIRECTOR

SUBJECT: Meeting of Black and Latino Employees on April 19, 1971

There will be a meeting of the Black, Latino and other concerned employees of the Stanford University Medical Center at 9 a.m., Monday, April 19, 1971 on the Medical School lawn. It is expected that this meeting will last approximately one-half hour.

In addition, meetings for Black and Latino employees will be held from 1 p.m. to approximately 3 p.m. in Rooms M104 and M112 of the Medical School.

This memorandum is to request Stanford University Hospital department heads to make provisions, if at all possible, for those Black and Latino employees who wish to attend, to do so.

Thank you for your cooperation in this matter.

STANFORD --Stanford University officials Monday (April 19) rejected demands by a coalition of employees asking for the resignation of the acting Medical School dean and two hospital administrators, but they agreed in principle to six of the demands and pledged to pursue aggressive policies "to make equal opportunity a reality" at the Stanford Medical Center.

Medical School officials also rejected a demand that Dr. Jose Aguilar, sole Chicano on the Medical School faculty, be given tenure.

On the demand that Sam Bridges be reinstated, the Hospital replied that Bridges has now agreed to a grievance procedure, expected to begin later this week.

Bridges is a Black hospital employee whose dismissal was cited as the reason for a recent demonstration at the Stanford Hospital.

Answers to the 11 demands were given by University Provost William F. Miller and Hospital Director Dr. Thomas A. Gonda at a morning rally attended by 250 persons on the Medical School lawn.

Miller said "The President (Richard W. Lyman) and I reaffirm our confidence in Dr. John L. Wilson as acting dean and executive officer of the Medical Center.

"In so doing we take note of the resolution of the Faculty Senate of the School of Medicine."

The Senate April 14 unanimously pledged its support to "constructive efforts to resolve our present difficulties" and urged all the constituents of the Medical Center to join together "to work toward equitable solutions under the continuing leadership of Dr. John L. Wilson."

Miller also expressed "our strong confidence in Dr. Thomas A. Gonda as director of the Hospital and in the Alianza Latina and the Black Advisory Committee as advisors to him." The two groups represent Hospital minority employees.

"It is important now that these groups work together and that they make progress by non-coercive means and through our normal channels. This is the only way in which we can come to lasting agreements," Miller said.

Miller was followed by Dr. Gonda who read the answers to the demands. He stressed that the "Hospital administration shares many of the goals of the workers," and "we look forward to constructive talks."

Demands included having the Black and Latin committee empowered to evaluate policies, practices, and procedures of all departments in the Medical Center, voting places be filled by minority delegates on the Hospital's administrative council, and that housekeeping assistants be able to use any restroom designated for Stanford employees.

STANFORD -- The ninth annual meeting of hospital residents in anesthesia will be held at the Stanford University Hospital April 24-25.

Limited to the western United States, the conference's emphasis is on the exchange of original research. The young doctors from several western states who are specializing in anesthesia will present their investigations in the form of papers. Thirty papers will be read, covering a wide range of problems and topics relating to anesthesia and its effects on humans and animals. Eighty residents are expected to attend.

Science writers from area papers are welcome to attend. Abstracts will be available at the meeting, which will be held in Room M106 at the Medical Center. Registration is at 8 a.m.

FOR IMMEDIATE RELEASE

STANFORD –

Prof. William Dement, one of the nation's leading sleep researchers, has helped create a scholarly "dream world" for students in Cedro House at Stanford, where he's a faculty resident this year.

Undergraduates at the house are working on 12 major sleep research projects, mostly of their own devising, traveling into largely uncharted territory.

Dr. Dement believes their work is contributing significantly to general knowledge about sleep.

The students, under Dement's direction, are learning a lot about scientific inquiry and practice from a first-rate teacher and they are incorporating it into their everyday thinking—a far cry from the straight lecture, forced laboratory style of schooling.

But it is not play. Rather, it is a new, involved way of learning and living. It makes the acquisition of knowledge and day-to-day experiences seem more of one piece, which perhaps is what education, ideally, should be about anyhow, according to many of today's educators and students.

The students are receiving credit, but they have chosen to do the projects on their own. Initially, Dement envisioned only an "undergraduate special" lecture course. (Undergraduate specials are not in the general curriculum, and do not fall under any particular discipline or department; frequently they are specialized courses found only in the professional schools. However, Stanford undergraduates are allowed up to 36 units of such courses, which are usually offered to them on campus more at the interest and instigation of an individual teacher or researcher, than on a more organized basis.)

Some of their sleep projects will be written up in the new *Stanford Quarterly Review,* which will publish significant campus research.

Why are the students studying sleep? Some answers:

"In his lectures, Dr. Dement just mentioned some things that hadn't been studied and it made us want to take them on. Then, we started to think of other projects to do, too," said Damian Augustyn of Seattle.

"Sleep is something that is so relevant to everybody. It's learning about ourselves," observed Dave Ellison from Chicago.

"Well, I've always been really interested in dreams. And Dr. Dement's so sharp, the chance to listen to him meant a lot. Then, he's helped us get into some things that I'd really been wondering about," said Bill Swartout from St. Louis.

Technically, it was relatively easy to begin the projects, Dement said. With so many students eager to learn, he loaned them an old leeg machine (which measures brain waves) and showed them how to use it.

Rob Young of Grand Junction, Col., who already is a whiz with electronic equipment, explained: "There's a standard instruction manual, and some other material that the doctor gave us. So we've read up on how to work it, and we've studied how to read the graphs with Dr. Dement's help."

(more)

Bill Swartout said, "We watched real carefully a movie Dement had made for medical students about how to attach the electrodes (the sensors applied to the subject that are hooked up to the EEG machine). Then the doctor gave us a hand at first. We can all get them on okay now."

More sophisticated researchers could well be put off or discouraged by the conditions imposed. The EEG machine is set up in a home-made lab in the basement under the dining hall at Wilbur. The lighting is not the best, the pipes make continual noises, and the early morning traffic sounds "*just* when the subjects should be into their deepest sleep" are a real hindrance.

But the students seem to take the poor working conditions in their stride.

"There's a time," Dement observed, "when learning can be a very viable thing. These young people here have lots of energy, endurance and capacity—later, maybe other pressures and demands get more in the way."

* * *

Details of the students' sleep research projects, with some of the questions they are attempting to answer, follow:

* **Joy Kelley from Birmingham, Mich.,** is studying the 90-minute rhythm of rest and activity that the body is believed to function on, whether asleep or awake. For one entire week, she was allowed to sleep for a half hour and was awakened, to stay up for one hour only.

"Though I am having weird dreams, all in all I feel fine," Miss Kelley said. She described her dreams "great material for a novel—not confusing or especially scary at the time, but so hard to describe afterward."

Dement believes the experiment might provide some answers to the puzzle of body rhythm of normal rest and activity. Scientists believe this rhythm is different from the Circadian, or "biological clock" whereby physiological processes in all living things undergo cyclic changes in a 24-hour period, approximating day and night.

* **There is a theory** suggesting that important information in the brain is processed computer-like during REM periods. REM (rapid eye movement) sleep is a phenomenon which occurs regularly during sleep and is regarded as essential to well being. The theory suggests that when a person is learning a major new motor skill, the need and amount of REM sleep might be increased.

Doug Stevens of Portland, Ore., is testing out the idea by wearing prismatic goggles for six hours daily over a period of time. The goggles, which he made himself, distort his vision, forcing him to learn how to walk in a different way. The students are checking to see if his sleep recordings show any increased REM activity.

* **Bill Swartout and Damian Augustyn** want to know if outside sounds get into dreams.

They now have some clear evidence that they do. Next, the students want to learn if the same sounds act differently under stressful conditions, and if there is a difference between sexes of what is heard or ignored. So far the students are convinced the brain does discriminate and choose, even in sleep.

During an experiment there was a humorous dream recall when, unknown to the sleeping volunteer, special sound effects were used. "I was sitting on a bench talking with this friend and all of a sudden he stood up and started to crow and I thought 'what the hell is going on,' " the dreamer reported. Just as he was dreaming, a tape recording of a rooster had been played.

* **Grant Heidrach of Peoria, Ill.,** is the first of several students to remain blindfolded for 35 waking hours. The purpose of this experiment was to learn if visual deprivation can affect dreams. The evidence showed that his dreams were considerably affected. He recorded intense dream sensations of movements, shapes and colors.

* **Some students wondered** if there is any relationship between meditation and sleep. They had heard that meditation lowers the requirement for sleep. Dave Ellison and his group are now testing the claim by recording brain waves of meditating and sleeping subjects to see if there is any difference.

(more)

* **Dream researchers** have always wondered about the content of dreams of normal, healthy children. Are they any different from adult dreams, and if so, is there a consistent content? "There is very little research in the whole area of healthy children's dreams. Almost everything is a hypothesis," said Doug Anderson of Orland, Cal.

Doug and his fellow investigators have been sitting nights with a number of staff and faculty children watching them sleep. When the children begin to show eye movements, they are in REM sleep, and they are awakened. Usually, good dream recall is obtained at this time. "The dreams of kids are beautiful in their own right—it's a thing in itself just to learn about them," said Anderson.

* **Narcolepsy is a condition** causing irresistible attacks of REM sleep of relatively short duration, usually less than 15 minutes. Sleep researchers, including Dement, are studying its cause and treatment. The little understood disease has fascinated Thom Massey of Los Angeles, a graduate student-counselor at Cedro House, and some of his colleagues. What do narcoleptics dream about? Massey believes that their systemic study of narcoleptics' dreams is the first that's ever been done.

He and his team work at the Sleep Disorders Clinic at the Medical Center, recording some of the narcoleptic patients being treated there, and awakening them during REM periods for dream recall. Massey reports that narcoleptics seem to have an entirely different dream content including marked dream occurrences of persecution.

* **Several students,** including Gordon Gray of Mountain View, are going to apply their scientific curiosity to more practical matters—water beds, and the question of whether they are beneficial to sleep. Dream content and general REM sleep activity while sleeping on a water bed will be carefully monitored over a period of time. "We are finding very willing volunteers," said Gray.

* **Rapid eye movements in sleeping infants** at Stanford University Hospital are being studied by Beverly Harris of Los Angeles and Vivian Gordon of East Palo Alto. Dement believes that if a sleeping infant does not have any eye movements, there may be something organically wrong. The two students are donning surgical gowns to check on babies four times a week.

So far, they have seen 190 babies, and they all had rapid eye movement sleep However, if there were a case of no movement, the nurses would be alerted to double check over a period of time. Then tests could be run on the baby, with the possibility of instituting corrective measures. Such a test, which is easy for nurses to do on a continuing basis, might save a lot of heartache later on," commented Miss Harris.

* **Tom Graf of South San Francisco** leads a student team looking into differences among persons who never remember their dreams from those who do. They hope to find out why such differences exist in the face of the universality of REM sleep. They have already observed that nonrecallers seem to have more rapid eye movement when asleep, although what this means is difficult to evaluate.

* **John Reed of Aguanga, Cal.,** is interested in the effects of sleep deprivation, and stayed awake for 75 hours. Every three hours during this time he was given tests lasting 45 minutes each. When the deprivation was over he was allowed no extra sleep. At least two other students will undergo the same tests to get an average effect of sleep deprivation on various body functions. Other tests are planned to check deprivation effects on strength and endurance.

* **There is even** a project on extrasensory perception for the "turned on" researchers. Two students, Duard Slattery of La Jolla, and Sue Campbell of Atherton, thought that it might be possible for ESP to influence dreams. And now while one sleeps, the other attempts to influence his dreams through thought concentration.

APRIL 23, 1971

TO: Administrative Council and Hospital Department Heads

FROM: Thomas A. Gonda, M.D.

SUBJECT: Statement of Further Developments in Hospital Policies

A number of issues concerning Hospital personnel policies and practices have been raised in the last two weeks. Some of these have been aired publicly in the form of a set of demands. Others have come to the attention of the Hospital administration by other means. I believe it is important that the Hospital employees be informed as to the current status of its activity regarding these policies and practices. The accompanying statement contains the announcement of new policies and the clarification and implementation of some existing ones.

STATEMENT OF FURTHER DEVELOPMENTS IN HOSPITAL POLICIES

I. Development of an Employee Advisory Council.

A. Recent events have dramatized the necessity to obtain more involvement of employees in the decision-making process. Consequently, the Hospital intends to establish an Employee Advisory Council composed of representative employees on a Hospital-wide basis.

B. The Employee Advisory Council will be created in such a fashion that all employees, regardless of race or sex, will have a voice in the decision-making process.

C. It is the desire of the Hospital to implement such a Council at the earliest possible time, subject to an appropriate definition of its composition and function. The creation of the Employee Advisory Council requires a detailed evaluation of various alternative approaches. However, to expedite its creation, a target date of September 1, 1971 has been established.

II. Evaluation of Existing Practices and Policies by Minority Committees.

A. The Hospital is strongly committed to the principle that minority employees be provided equal employment opportunity. The Black Advisory Committee and the Alianza Latina shall have the right to receive and evaluate any complaints dealing with existing practices and policies regarding minority affairs.

It is expected that as a result of the evaluation of such complaints the Black Advisory Committee and the Alianza Latina will make constructive recommendations.

B. Recommendations made by the Black Advisory Committee and the Alianza Latina will include a detailed analysis of the present practice or policy and suggested procedures for implementation of the recommendations.

C. The Hospital is now developing an Affirmative Action Program to help solve present and any future minority employee problems. The analysis and recommendations of the Black Advisory Committee and the Alianza Latina should serve as a continuing influence regarding solution of minority employee problems.

-more-

III. Composition of the Hospital Administrative Council.

In order to have advisory input by minorities on Hospital matters, two additional full appointments are being made to the Hospital Administrative Council. These seats are to be occupied by the senior Black staff member and the senior Latin staff member in the Administration Department.

IV. Revision of Grievance Procedure Policy.

Any Hospital employee, whether permanent or probationary, may use the Grievance Procedure when he has a complaint relating to his employment.

V. Posting of Job Openings for Employee Advancement.

The Hospital will post notices of all employee job openings on the Personnel Department bulletin board and on the Cafeteria bulletin board. These notices will contain the starting salaries for the position.

VI. Implementation of Job Classification and Evaluation.

A. The Hospital is presently making a job audit to clearly define the duties of various positions within the Hospital. Salary ranges will be indicated on each job classification.

B. The Hospital will continue its policy of evaluating employees at regular intervals. A copy of each evaluation will be given to the employee involved and he will be expected to sign the evaluation form. To avoid any misunderstanding concerning the requirement that the employee sign the form, there will be on all such forms a notation to the effect that the employee acknowledges receipt of a copy of the form, but does not indicate by his signature that he agrees with the substance of the evaluation.

VII. Clarification of Leaves of Absence.

A. Request for leave of absence is to be made on a "Leave of Absence Authorization" form. A form is in preparation. In completing this form, the employee shall provide a description of the reasons for which the leave of absence is sought and appropriate documentation of these reasons.

-more-

VII. (continued)

B. The Hospital will make every effort, including such procedures as hiring of temporary personnel, to assure that an employee who has been on leave of absence is reinstated to the job which he occupied immediately prior to taking the leave of absence.

C. To inform the employee prior to beginning his leave of absence about his reinstatement status, the Department Head will note one of the following on the "Leave of Absence Authorization" form:

1. "Same position guaranteed";
2. "Similar position guaranteed";

VIII. Modification of Employee Medical Insurance Program.

The Personnel Department has been directed to prepare and circulate questionnaires concerning the desirability of Hospital-provided spouse medical insurance coverage, along with other alternatives under the Hospital's medical insurance policies. The findings of this survey will be the basis of further modification of our employee medical insurance program.

FOR IMMEDIATE RELEASE
STANFORD –

STANFORD UNIVERSITY NEWS SERVICE

Shortly before 4 a.m. Friday, an explosive device with a timer exploded in the attic of the president's office building at Stanford University, causing moderate damage.

Campus security guard George Curry, on the second floor no more than 30 feet away when the device exploded, said "I haven't heard anything like this since Korea." His ears still were ringing an hour later, he said, but he was not otherwise injured.

The device punched a two-foot diameter hole in the ceiling near two second-floor offices occupied by legal advisers to the president. Several pieces of red tile roof were knocked to the ground, and many others were damaged. Damage initially was estimated by Fire Chief Frank Jurian at $5000.

The FBI took charge of the investigation.

At 11:22 p.m. Thursday five bullets were fired at a PG&E transformer compound near the Women's Gym. Two bullets penetrated two transformers, causing an oil leak. Students informed police and firemen, who stopped the leak. Had the leaking continued, a mild explosion might have taken place, firemen said.

About half an hour before the explosion in the president's office, *Stanford Daily* and KZSU reporters reported seeing two persons, possibly female, running past the office. They were believed to be involved with the placing of revolutionary posters in many places on the campus during the night, and an attempt had been made to paste one on the office door.

At 3:35 p.m. Thursday afternoon Palo Alto police received an anonymous call from a male voice saying "a bomb will go off in 30 minutes in the Stanford area." The bomb in the president's office building exploded at 3:54 a.m. Friday, about 12 hours later.

It was not immediately known whether either the call or the posters were directly linked to the incident. For months the building has been guarded on a round-the-clock basis after normal working hours.

How the bomb was placed in the attic was not known. The two-story structure, located in Inner Quad, sustained more than $100,000 damage in an arson-caused fire July 5, 1968.

The explosion scattered plaster and debris over a 20-foot radius on the second floor, but employees were admitted to the building on arrival for work. The personal office of President Richard W. Lyman is located on the first floor.

Commenting on the incident, President Lyman said: "Naturally I am angry at this senseless act. Everything possible is being done to find out who did it. We need the cooperation and help of all at Stanford to bring to end such harassing attacks upon the University."

The posters protested "an undeclared, racist and aggressive war" and charged that Stanford has placed the "welfare and life of the Stanford professor above that of the Stanford worker."

"Where racism and injustice penetrate the very fabric of the institution, merely to question the established order is to rip that fabric asunder," the poster added. "It is no wonder then that Sam Bridges [was fired], Dr. Aguilar denied tenure, Bruce Franklin sacked and hospital workers brutalized in an unprovoked pig attack" (Photos show demonstrators clubbing police before officers responded).

"The power to build a humane and just society lies within the people," the poster added. "Support the workers, Power to the righteous."

STANFORD -- Stanford University Hospital Saturday announced that effective immediately, Black and Latin employee representatives will sit on its administrative council as part of new personnel policies and practices being put into effect.

The seats on the council will be occupied by the senior Black staff member and the senior Latin member in the administration department.

Disclosure that the Hospital is moving forward to implement minority demands, accepted April 19, was made in a memorandum to hospital department heads by Dr. Thomas A. Gonda, hospital director.

Dr. Gonda wrote the appointments were being made to provide "advisory input by minorities on Hospital matters." Representation on the council, a Hospital advisory body, was a key minority demand.

"I believe it is important that the Hospital employees be informed as to the current status of its activity regarding these policies and practices." Dr. Gonda wrote.

The Hospital director announced the following new policies:

. The Hospital will establish a broad advisory council to assure that all employees, regardless of race or sex, will have a voice in the decision-making process. The target date for establishing the council will be September 1, 1971.

. The Black Advisory Committee and the Alianza Latina will evaluate practices and policies associated with minority affairs at the Hospital.

. All Hospital employees, regardless of length of employment, will have the right to a grievance procedure.

. Job openings will be posted on bulletin boards, along with starting salaries for each position.

. The Hospital will make every effort to assure that an employee who has been on leave of absence is reinstated to the job originally occupied. When an employee's leave is approved, the department head will note one of the following on the authorization form, "same position guaranteed," or "similar position guaranteed." If the position cannot be guaranteed, it will be so stated in advance.

. The Personnel Department will circulate questionnaires concerning the desirability of instituting medical insurance coverage for the spouses of all Hospital employees. The findings will be used as the basis for further modification of the employee medical insurance program.

A job audit to classify various positions in the Hospital is under way.

BUSINESS WIRE; 4-26-71

STANFORD -- In the face of a morning walk out by Black employees, Stanford University Hospital officials took steps Monday afternoon to maintain patient care services, and stressed that employees who stay away in support of a work stoppage will not be paid.

Dr. Gonda, Hospital director, referred to a flyer distributed throughout the Hospital Monday morning by an unidentified group, which said employees engaging in a work stoppage over grievances cannot be replaced.

"That is not the law," Dr. Gonda stated in a memorandum issued to hospital employees and medical staff. "The Hospital has a grievance procedure. Employees who stay away from work over grievances can be legally replaced."

The Hospital director added: "I want to emphasize that employees who stay away from work in support of the so-called work stoppage will not be paid for time away from work."

He also said that hospital employees on their shifts are expected to perform their hospital duties. "So far as meetings are concerned, they will be expected to attend only designated official Hospital meetings. Employees who attend unofficial sessions or rallies will do so on their own time.

Dr. Gonda said that in the past two and a half weeks, the Hospital has been subjected to a sit-in, which ended in great damage, to bomb threats and "its employees have been threatened and intimidated."

"This is intolerable," Dr. Gonda said. "We remain ready to contin to reach rational solutions with our employees on any Hospital issues that are of concern to them, but not with disruptive forces who want to destroy our hospital."

4-26-71 Gonda p. 2 5:30 pm.

Earlier Dr. Gonda issued a statement saying that a group which styles itself as the Stanford University Medical Center Coalition "does not represent minority employees at the Hospital."

He said the legitimacy of the coalition is in question, and this made difficult for the Hospital to respond "appropriately and effectively to the issues, and to enter into binding agreements regarding hospital minority employees."

"The fundamental issue," Dr. Gonda said, "is the legitimacy of the group that purports to represent hospital minority employees.

"This group claims to represent a self-defined coalition that includes some minority employees of the Hospital and University, but also a large number of persons who are not University or Hospital employees.

"Many workers have made it clear that the Stanford Medical Center Employees Coalition does not, in fact represent the minority employees of Stanford University Hospital."

Dr. Gonda noted the Hospital has already initiated those improvements agreed upon in previous discussions with Hospital minority employees, and will continue to do so with all speed.

He said a numbeer of Black employees who stayed away Monday "have telephoned in and told us ~~that~~ they have been subject to coercion, intimidation and threats to keep them away from the Hospital."

Meanwhile Latin employees at the Hospital remained on the job, and declined to ~~issue a statement~~ comment about their plans after a meeting this afternoon.

Several hospital departments were hit hard by the stoppage, including housekeeping, diatary and diagnostic radiology. Since employees were scheduled to work different shifts throughout the day it was impossible to determine the exact number of employees who were abse

The Hospital received a bomb threat around noon, the third such incident since police ended the occupation of its administrative offices April 9 in which 23 persons, mostly white were arrested. Only one of those arrested was a Hospital employee. Most of the others were from outside the University.

Leaflets distributed by 20 pickets outside the Hospital Monday morning said that Black workers had voted Friday to stop work until the administration agrees to meet the demands. They carried signs calling for "Amnesty for the Hospital 23," "Rehire Sam Bridges," "Stanford Is a Racist Institution," and "Grant Dr. Aguilar Tenure." Many of the pickets wore Venceremos and Black Liberation Front buttons.

Bridges, whose firing after several weeks' employment precipitated the Hospital demonstration, was one of the picketers outside the Hospital this morning.

During the sit-in, Hospital officials asked Bridges to take part in established grievance procedures, but he declined. The offer was renewed after the disruption, and on April 15, he notified the Hospital that he would consent to a hearing. He was told the next day that the hearing was set for April 22. On April 20, however, Bridges stated in an open letter to the community that he had been fired for unsubstantiated charges, and that he should be reinstated.

Dr. Aguilar is a Chicano neurosurgeon who did not receive reappointment after six years on the Stanford faculty. The Medical School said Dr. Aguilar's case was reviewed twice at his request, and by the University Provost's office and no irregularities were found in the decision not to reappoint him.

STANFORD - Many black workers at Stanford University Hospital walked off their jobs Monday morning, April 26, in a work stoppage "to protest the failure of the Hospital Administration to meet minority demands" presented earlier this month.

Latin-American workers at the hospital tentatively elected to remain on the job, with a meeting scheduled for 3 p.m.

Leaflets distributed by 20 pickets outside the hospital said that black workers at the hospital had voted Friday to stop work until the administration agrees to meet the demands.

Saturday morning, however, the hospital announced that it was moving forward to implement six of the demands concerning workers' rights, including greater voice for minorities in the hospital's decision making.

There are 317 blacks and 133 Latin Americans employed at Stanford Hospital out of a total of 2,170 employees.

Since the employees were scheduled to work different shifts throughout the day, it was impossible to determine the exact number of minority employees who were absent from their jobs.

Several departments were hard hit by the stoppage, including housekeeping, dietary and diagnostic radiology. Virtually all of the 34 minority employees in housekeeping had gone home early Monday morning.

Pickets carried signs calling for "Amnesty for the Hospital 23"; "Rehire Sam Bridges"; "Stanford is a Racist Institution"; and "Grant Dr. Aguilar Tenure!"

Bridges, whose firing after several weeks' employment precipitated the hospital demonstration, was one of the picketers outside the hospital this morning.

Bridges, a black employee whose dismissal was cited as a cause of the April 9 hospital sit-in, phoned hospital officials April 15 and said he would consent to a grievance procedure. On April 16, he was informed a grievance hearing would be held April 22 and requested to list those persons, both employees and outsiders, whom he wished to have accompany him. He also was asked to submit a written grievance by April 19. He did not do so, but instead requested reinstatement with back pay.

Early in the controversy, United Stanford Employees filed a complaint on his behalf with the National Labor Relations Board.

Heart Transplant #31

Herbert G. Juster, 48, of South Braintree, Massachusetts, became the 31st heart transplant recipient at Stanford University Hospital late Saturday night, April 24, 1971.

Juster is a retired engineer and is married. The donor is anonymous.

Juster is in satisfactory condition.

The operation was performed by a team headed by Dr. Norman Shumway. Of the 31 recipients, 11 are now surviving.

STANFORD UNIVERSITY HOSPITAL
Office of the Director

April 26, 1971

TO: ALL HOSPITAL EMPLOYEES AND MEDICAL STAFF

FROM: Thomas A. Gonda, Director, Stanford University Hospital

We regret that some employees have seen fit to stay away from work today. We shall do our best to operate the Hospital with no interruption in patient care.

A number of Black employees who have stayed away have telephoned in and told us that they have been subject to coercion, intimidation and threats, to keep them away from the Hospital.

We ask all employees to do their best in the interest of our patients and request all employees who have stayed away to return to work on their next scheduled shift.

Hospital employees on their shifts are expected to perform their Hospital duties. So far as meetings are concerned, they will be expected to attend only designated official Hospital meetings. Employees who attend unofficial meetings or rallies will do so on their own time. They will not be paid for participating in such unofficial activities.

Speaking of pay, I want to emphasize that employees who stay away from work in support of the so-called work stoppage will not be paid for time away from work.

A flyer issued by outside groups says that employees who engage in a work stoppage over grievances cannot legally be replaced. That is not the law. The Hospital has a grievance procedure. Employees who stay away from work over grievances can legally be replaced.

The Hospital has tried and will continue to try to resolve problems on a rational basis. Toward this end, minority employees obtained a room within the Hospital to use as an Information Center. The room was almost immediately commandeered by outsiders for their purposes rather than those of the Hospital employees. This practice can no longer be condoned, and the room has been returned to regular scheduling.

It is important that all employees rededicate themselves to our primary responsibility for enabling the Hospital to continue to provide the best possible patient care.

In the past two and a half weeks, the Hospital has been subjected to a sit-in, which ended in great damage, to bomb threats, and its employees have been threatened and intimidated. This is intolerable. We remain ready to continue to try to reach rational solutions with our employees on any Hospital issues that are of concern to them, but not with disruptive forces who want to destroy our Hospital. ###

FOR IMMEDIATE RELEASE

STANFORD - In the face of a morning walk out by black employees, Stanford University Hospital officials took steps Monday afternoon, April 26, to maintain patient care services and stressed that employees who stay away in support of work stoppage will not be paid.

Spot checks in several departments indicated that more than one half the black employees on the afternoon shift worked, compared to less than one fourth of the morning shift.Meanwhile, Latin employees remained on the job at the hospital, and declined to comment about their plans after a meeting Monday afternoon. Monday night, United Stanford Employees renewed its appeal for support of the work stoppage.

A flyer distributed throughout the hospital Monday morning by an unidentified group said employees engaging in a work stoppage of grievances cannot be replaced.

"That is not the law," Hospital Director Dr. Thomas Gonda stated in a memorandum sent to hospital employees and medical staff. "The hospital has a grievance procedure. Employees who stay away from work over grievances can be legally replaced."

The hospital director added: "I want to emphasize that employees who stay away from work in support of the so-called work stoppage will not be paid for time away from work."

He also said that hospital employees on their shifts are expected to perform their hospital duties. "So far as meetings are concerned, they will be expected to attend only designated official hospital meetings. Employees who attend unofficial sessions or rallies will do so on their own time."

Dr. Gonda said that in the past two and a half weeks, the hospital has been subjected to a sit-in, which ended in great damage, to bomb threats, and "its employees have been threatened and intimidated."

"This is intolerable," Dr. Gonda said. "We remain ready to continue to reach rational solutions with our employees on any hospital issues that are of concern to them, but not with disruptive forces who want to destroy our hospital."

Earlier, Dr. Gonda issued a statement saying that a group which styles itself as the Stanford University Medical Center Coalition "does not represent minority employees at the hospital." He said the legitimacy of the coalition is in question, and this made it difficult for the hospital to respond "appropriately and effectively to the issues, and to enter into binding agreements regarding hospital minority employees."

"The fundamental issue," Dr. Gonda said, "is the legitimacy of the group that purports to represent hospital minority employees. This group claims to represent a self-defined coalition that includes some minority employees of the hospital and University, but also a large number of persons who are not University or hospital employees.

"Many workers have made it clear that the Stanford Medical Center Employees Coalition does not, in fact, represent the minority employees of Stanford University Hospital."

Dr. Gonda noted that the hospital already has initiated those improvements agreed upon in previous discussions with hospital minority employees, and will continue to do so with all speed. He said a number of black employees who stayed away Monday "have telephoned in and told us they have been subject to coercion, intimidation, and threats to keep them away from the hospital.

Several hospital departments were severely affected by the Monday morning stoppage, including housekeeping, dietary, and diagnostic radiology.

The hospital received a bomb threat around noon, the third such incident since police ended the occupations of its administrative offices April 9 with the arrest of 23 persons, mainly whites. Only one was a hospital employee. The majority came from outside the University.

Leaflets distributed by 20 pickets outside the hospital Monday morning said black workers had voted Friday to stop work until the administration agreed to meet the demands. Their signs called for "Amnesty for the Hospital 23," "Rehire Sam Bridges," "Stanford Is a Racist Institution," and "Grant Dr. Aguilar Tenure." Many of those picketing wore Venceremos and Black Liberation Front buttons.

Bridges, whose firing after several weeks employment was cited as a cause for the sit-in, was one of the picketers. During the sit-in, hospital officials asked him to take part in established grievance procedures, but he declined. The offer was renewed after the disruption and on April 15 he notified the hospital he would consent to a hearing. He was told the next day the date was set for April 22. On April 20, however, Bridges stated in an open letter to the community that he had been fired for unsubstantiated charges and should be reinstated.

STANFORD UNIVERSITY HOSPITAL
Office of the Director

April 27, 1971

TO: Stanford University Hospital Employees and Medical Staff
FROM: Thomas A. Gonda, M.D., Director

In response to broadly elicited advice and in the light of clarification of issues with the passage of events, the Hospital Administration presents the following reformulation of its position with respect to discussions regarding terms and conditions of employment of Hospital employees:

The Hospital Administration looks forward to the establishment of a representative employee council with which it can consult on issues affecting Hospital employees. In the final analysis, only the widespread participation of all employees can ensure successful implementation of programs, including such vital programs as "Affirmative Action."

In the meantime:

(1) The Hospital Administration is prepared to meet with and take seriously the advice given by any group of Hospital employees on any Hospital-related issue. In such meetings employees may have advisors present within a framework of orderly discussions.

(2) The Hospital will negotiate Hospital-related issues only with groups that can demonstrate that they actually represent the employees who would be affected by agreements reached in the negotiations.

(3) The Hospital does not recognize the "Stanford Medical Center Employees Coalition" as an appropriate bargaining unit nor their representatives as negotiators.

STANFORD -- Licensed vocational nurses at Stanford University Hospital will vote whether they wish to be represented by the California Licensed Vocational Nurses Association in collective bargaining in an election May 3, hospital director of personnel Kenneth Dunkle announced today.

The election, which will be supervised by the California State Conciliation Service, "will determine whether or not the organization will represent the Stanford LVN's in matters of wages, hours, and working conditions," Dunkle said. There are currently 51 LVN's at Stanford.

The election will be held in Room W001 by secret ballot from 6:30 to 7:30 a.m., and 1:30 to 3:30 p.m. on Monday, May 3. Notices will be posted throughout the Hospital for several days prior to the election.

The vote was scheduled after the CLVNA, claiming support from a majority of the LVN's at Stanford, wrote the Hospital asking for an election. Several Hospital nurses had contacted the organization and expressed interest in obtaining representation.

The last election of this type at Stanford Hospital was held March 30, 1967, when Hospital and Institutional Workers Union, Local 250, unsuccessfully attempted to organize all nonprofessional hospital workers. -30-

STANFORD -- A small grant to study the effects of bunker oil on aquatic birds has been awarded to the Stanford University School of Medicine by Standard Oil of California.

This is one of the first such investigations to be made; apparently there has been little previous systematic research on the toxic effect of oil on birds.

Included will be pathology, microbialogy and tissue toxicity studies. A distinction will be made between the birds actually dying from an oil spill itself and from secondary causes, such as infection, malnutrition and reaction to captivity.

Two postdoctoral fellows at the Animal Care Facilities at Stanford, Dr. Bret Snyder and Dr. James Fox, will conduct the research with the $6,400 grant.

At the time of the recent massive oil spill in the San Francisco Bay, the young doctors offered, on their own, their diagnostic services to the San Francisco Zoo, where many of the oil soaked birds were being sent.

They soon had over 100 tissue specimens from birds that had already died.

They informed Standard Oil that they had such a collection and would like funds to do further research. This request has now been granted.

"We are going to make a systematic attempt to find out about the interrelated causes of death," Dr. Snyder commented. "It's primarily a field study. There has been a lot of simplification about why the birds actually died, but this study should make a start in sorting out all the factors."

Dr. Snyder and Dr. Fox are working with disease diagnosis and treatment of research animals at the Animal Care Facilities at Stanford.

STANFORD –

The secrets of alcohol addiction can now be probed more efficiently than ever before through a simple system developed by a Stanford University scientist. The system produces rapid alcohol dependence in mice and permits withdrawal reactions to be observed and measured.

This new approach to the study of alcoholism owes its existence to the work of Dr. Dora B. Goldstein, a senior scientist in the Department of Pharmacology of the Stanford University School of Medicine.

Dr. Goldstein explained that scientists have been trying for some time to develop an animal model that would help them understand the addiction process. The model is also needed because certain kinds of information cannot be obtained by studying alcoholics.

"Alcohol addiction in man develops over a period of years, and it is accompanied by malnutrition and disease," Dr. Goldstein said. "It is difficult to study alcohol dependence when other diseases are present."

Of all the animals used for studies of alcoholism, mice seemed to be best because they can become alcoholic in two to four days compared to about two weeks in the more expensive animals such as dogs and monkeys, she said.

The hitch, however, was that mice eliminate alcohol very rapidly and it has been difficult to maintain high blood alcohol levels by injection in their system.

Dr. Goldstein solved the problem by a simple approach. She administers the alcohol by inhalation, housing the mice (with food and water supply) in a transparent, air-tight plastic box to which alcohol vapor is pumped continuously.

The mice are removed by the scientist twice a day to weigh them, take blood samples, and inject pyrazole, a chemical that slows down alcohol metabolism, and assures constant blood alcohol level for the production of physical dependence.

After a few days in the chamber, the mice are removed and their falling blood alcohol is measured every two hours. The mice are observed continuously, with scores of the severity of withdrawal reaction recorded at intervals until the alcohol disappears from their blood and they recover. Typical signs observed in the mice are similar to those occurring in alcoholics who have stopped drinking—lethargy, trembling, jumpiness and convulsions.

Dr. Goldstein explained that "addiction is believed to be a result of the body responding physiologically to the effects of the drug on some target organ, most likely the brain, and adapting to it.

"In an adapted system, the organism functions well as long as the blood level of alcohol remains constant.

"When the drug level in the blood drops, the organism is out of balance. Withdrawal symptoms may be a display of an adaptation that is no longer appropriate because the drug stimulus is no longer there."

Dr. Goldstein said scientists do not yet know what biochemical system is involved in alcohol addiction, but "we can measure how long the body takes to adapt to alcohol, and to recover after it has been taken away.

"When we get an idea of what has changed biochemically for the body to make the adaptation, and if we can show that such a change follows the same time course as the adaptation process, we may have a clue to the alcohol addiction problem."

Other goals of Dr. Goldstein's research, supported by the National Institute of Mental Health, are:

* to test drugs that modify withdrawal symptoms and can be useful in therapy of alcoholics.
* to better understand what kinds of drinking patterns are dangerous and can lead to alcoholism, and
* to show genetic differences. (For example, if male and female drinkers may become equally dependent from the same amount of alcohol.)

Dr. Goldstein's work is reported in a paper titled 'Alcohol Dependence Produced in Mice by Inhalation of Ethanol: Grading the Withdrawal Reaction," in the current issue of *Science* magazine. –30– 4/29/71

STANFORD —

Dr. Philip Sunshine, director of nurseries at Stanford University Hospital, Thursday, April 29, urged passage of a new California State Assembly bill which would require insurance companies to cover newborn infants from the moment of their birth.

"This type of legislation is long overdue," he said. "I believe it is imperative that this bill be passed."

In an interview, Dr. Sunshine voiced his strong support for the bill, introduced into the California legislature by Assemblywoman Yvonne Brathwaite of Los Angeles. He was prepared to appear at a hearing before the Assembly Committee on Finance and Insurance Wednesday, April 21, but testimony was not needed as the bill passed without opposition to the Assembly floor. A vote is expected some time in the next few weeks.

Dr. Sunshine has long been an outspoken proponent of compulsory reform in existing insurance policies, the majority of which do not cover infants until they reach 14 or 30 days of age. Such policies offer little help in paying the staggering medical costs which are faced by parents of premature infants and parents of babies afflicted with debilitating diseases.

Stanford Hospital, the referral nursery for the Mid-Peninsula and San Jose area, receives many premature infants because of problems that can't be handled by other area hospitals. Dr. Sunshine estimated that the Stanford nursery treats approximately 700 premature infants per year, some flown in from as far away as Fresno and Lake Tahoe.

The most common illness which affects premature infants is respiratory distress syndrome (RDS), a disease of the lungs occurring in approximately 20 percent of all premature babies. Dr. Sunshine said that the parents of an infant afflicted with RDS, receiving little or no aid from insurance policies, will have an average hospital cost of $2,500-$2,800.

"The important point is that most people have insurance policies and think they are fully covered," he said. "Then they read the fine print and find out that their baby isn't covered until he has lived 14 or 30 days. Today, with intensive care nurseries, the cost can reach $200 or more per day. This adds up to $2,800 for the parents with the 14-day policy, or at least $6,000 for those with the 30 day policy."

Assemblywoman Brathwaite's bill, introduced Feb. 24, would require that any insurance company offering comprehensive, group or family health, or disability insurance, must also cover the newborn infant from—and after—the moment of birth. In fact, companies would no longer be able to exclude coverage of a newborn infant for 14 or 30 days.

Dr. Sunshine stressed that the cost for such insurance, when compared with the burden many families are now forced to bear, would be minimal.

"The cost per family to have this insurance, providing the bill is passed, would be about 60 cents per month," he said. "But even if it was $2 per month in total coverage, it would still be worth it. Presently at Stanford, less than 25 percent of our babies who have RDS have adequate coverage."

At Stanford and other intensive care nurseries, many new techniques are being developed and utilized to give prematurely born and sick infants an optimal chance for survival.

"These infants are carefully monitored to insure their serum chemistries and acid-base status are maintained within normal limits," Dr. Sunshine said. "Careful temperature control, early detection of cardiorespiratory abnormalities, and sophisticated surgical techniques have also been perfected."

Recent studies have indicated that when the smaller premature babies are cared for in this manner, the incidence of neurological and intellectual impairment is markedly decreased.

In addition, Stanford and other centers are encouraging parents to become involved in the care of their premature infants soon after birth, and in this manner, the parents are better able to care for their infants when they are released from the hospital.

"Nowadays, we often don't wait until the babies reach five and one-half pounds to discharge them," Dr. Sunshine said. "We've often sent babies home who weigh less than four pounds to be cared for in modified home incubators, and with the aid of visiting and public health nurses."

STANFORD--Two new administrative appointments have been announced at Stanford University Hospital.

Dr. Thomas A. Gonda, hospital director, announced the addition of Emil Strom as consultant in hospital planning and health care services, and John G. Williams as associate director of the hospital for patient care services.

Strom joins the University hospital after 18 years as a member of the California State Health Department. As a representative of that department's Bureau of Licensing and Certification in 1959, he played a major role in the original licensing of Stanford Hospital when the Medical Center opened. His work with the State included developing the methods of evaluating hospitals, nursing homes and clinics, as well as helping to set standards thay must meet for licensing and certification.

His role at Stanford is to study systems of health care delivery in relation to possible future expansion of facilities and services at the University hospital, and to advise the hospital in the areas of health insurance and current health legislation.

Strom is a 1948 graduate of Hamline University in St Paul, Minnesota. He received the M.A. in musicology at the University of California at Berkeley in 1951 and is a teacher of piano and composition.

A resident of Mountain View, he is serving in his fourth year on the advisory committee for long-term care of the Santa Clara County Medical Society.

John G. Williams comes to Stanford from the University of Utah Hospital, where he has been assistant administrator. He went to Salt Lake City in the summer of 1969 after obtaining the M.P.H. at the University of California at Berkeley.

At Stanford, he will serve as liaison with the medical staff, and will be the administrative director of the hospital's 26 clinical laboratories and patient care service departments.

Williams is a native of San Francisco. He received the B.S. in Business Administration from the University of San Francisco in 1967. While in the master's degree program at Berkeley he took an administrative residency at the University of California Hospitals in San Francisco.

He is married to the former Mary Ball of Berkeley, and they have a two-year-old son. The family moved into a new home in Cupertino in mid-April.

STANFORD--A new program for monitoring the body concentration of important therapeutic drugs has been developed by a research team at Stanford University Hospital.

Dr. Paul Wolf, director of clinical laboratories, and Dr. Sumner Kalman, professor of pharmacology at the University School of Medicine, announced today (May 26) that the program is now being made available for use in the clinical laboratories at the Hospital.

"Our purpose," Kalman explained, "is the detection and measurement of drugs administered to a patient, and the determination of how his body handles them. This allows doctors to more effectively maintain proper drug levels in the patient's bloodstream."

In adjusting drug dosage, the rate of metabolism of different drugs from patient to patient will be taken into account, he added.

Kalman gave major credit for the research of the new system to Eric Watson, a chemist in his laboratory, and assistance from Wolf and his associates in the clinical laboratories.

Over the years, the major area of interest in the clinical laboratories has been the detection of toxic drugs a patient took. This usually required several hours because of tedious manual procedures, and often samples of a patient's blood had to be sent to reference laboratories.

At Stanford, due to much more rapid extraction, separation and gas chromatography techniques, the emphasis will now shift toward monitoring drugs administered to patients by clinicians at the Hospital.

"In the past we've been primarily concerned with drugs taken by an individual with suicidal intent," Wolf said. "The advantage of this new system is that we specifically know the level of the therapeutic drug in a patient's system and whether he is responding to the drug at that level."

The technique involves the use of a highly-sensitive instrument called a gas chromatograph (GLC), operated by medical technologist Jenny Meyer, which measures the amount of a drug present in the patient's blood.

A sample of the patient's blood is extracted and injected into the GLC, which turns the drugs in the sample into a gas phase through the application of intense heat.

The drugs in the gas phase are separated because they pass through the column in the GLC at different speeds. After a specific drug moves off the column it is ionized by flame, at which point the detector is capable of reading the amount of the drug present in the blood. Finally, a read out on the GLC's paper chart-recorder reveals the specific amounts of each drug.

This measurement, along with considerations of the patient's condition and his rate of metabolism, will enable doctors to adjust dosage when necessary and maintain the proper level of drugs in the patient's body.

"Our major push," said Wolf, "is to determine the specific amount of a drug for a specific illness and a specific patient."

-more-

"This program will help us develop guides for rational dosage-scheduling of drugs," Kalman said. "Doses need to be fitted to individual needs. There is no average man who always need 400 mg of drug A or 100 mg of drug B on a certain daily schedule."

Last week Hospital clinicians began applying this technique in the detection and measurement of commonly used sedative drugs. The process takes only 45 minutes.

However, the primary impact of the program will be felt in the near future, when it is used in the detection of important drugs used in the treatment of heart disease. This, as Kalman explained, was where his research started.

"I've been interested for two or three years in developing a program like this," he said. "I decided to start with drugs that are used in treating heart disease--the digitalis group. We need this system because the amounts of digitalis in the patient's blood are very small. Its concentration in the bloodstream is among the lowest of important drugs."

Digitalis is widely used in the treatment and control of heart failure. A patient who has heart failure may have to take this drug for the remainder of his life. Another more sensitive gas chromatogra equipped with an electron capture detector, determines how much digitalis is present by utilizing other chemical methods.

"In this way," Wolf noted, "the patient will be monitored during the course of heart failure so that he'll get only the required amount of digitalis. There will be little chance of an overdose. The program will enable us to answer important questions such as whether the patient still is in heart failure, whether he has drug constancy, whether there are problems with metabolism of the drug, and whether the dosage should be altered."

Kalman's research team, supported by a grant from the National Heart Institute, has also been working on the detection of lidocaine, a drug used to control cardiac arrhythmias, that is, disturbances of rhythm of heart beat. This technique will also soon be put to use in the Hospital's clinical labs, perhaps by next week.

"In the future we hope to expand the program further and develop new methods of drug detection in human metabolism for all of the commonly used important drugs," Kalman said.

STANFORD--Dr. Norman Shumway, who pioneered heart transplants at Stanford University Hospital, has begun a program to meet what he calls "the greatly increased demands of cardiac patients" by helping develop new open-heart surgery centers at two San Francisco Peninsula hospitals.

Open-heart operations have more than doubled at Stanford University Hospital since 1965. During the past year, the number of such operations has further skyrocketed because of a new surgical technique to aid persons with coronary artery ailments, by far the most common form of heart disease.

"It is time for coronary artery surgery and heart valve replacement to come out of the university and into community hospitals," Shumway said.

Shumway has already assisted in putting together a surgical team at El Camino Hospital in Mountain View. He hopes to repeat the procedure at Peninsula Hospital in Burlingame in what he said is a "natural evolution" away from Stanford hospital. The Peninsula hospital medical board is reported to be considering Shumway's proposal.

New surgical units will handle all forms of heart surgery except experimental surgery such as heart transplants.

Shumway said he plans to do fewer routine open-heart operations to devote more time to experimental surgery and teaching. Transplants should remain at Stanford, he believes, because of "their highly investigational nature--there are still too many things we don't know about this particular procedure to let it get too far away."

The surgeon hopes satellite centers will play a big role in expanding bed space available on the Peninsula for a rapidly growing number of heart patients needing surgery. He said the idea represents a new approach, since with few exceptions, open-heart surgery nationwide today is performed by university-affiliated teaching hospitals.

Until recently Stanford Medical Center has been trying to meet the needs of most of these people with only about 200 beds, "far too few," according to Shumway.

In his view, branching out into community hospitals relieves pressure for surgical facilities, very often felt by university hospitals, provides better bed utilization of area hospitals, and opens more room for pure research and development at the academic centers.

Shumway hopes his dispersal program will begin a pronounced movement which will include the establishment of medical centers in rural and even suburban areas that could extent the latest advances of open-heart surgery to more people.

With improved communication, he expects that surgeons in every part of the country will be able to keep up on the latest methods, and could in addition periodically come to research centers such as Stanford for short stays.

The program of decentralization involves several surgeons trained by Shumway. One heads up the open-heart surgery program at the Palo Alto Veterans Administration Hospital. Two other surgeons are in the process of leaving the Shumway staff to go into private practice in Palo Alto. They will be able to admit routine open-heart cases to the community bed section of the Stanford hospital.

Still other Stanford-trained heart surgeons are expected eventually to take over the satellite operations at El Camino and Peninsula hospitals. All of them will continue their Stanford association as volunteer faculty members.

Shumway said he has no plans of his own for going into private practice. He said he enjoys the academic life "because there's time for everything--research, teaching, and the actual surgery."

###

STANFORD--Dr. George J. Laird, 56, of Burlingame, is the new president of the Stanford Medical Alumni Association, and Dr. Theodore W. Loring of Eureka, is the new president-elect.

Laird, who will serve as president from now through June 1, 1972, is a general surgeon. He received his M.D. degree from Stanford in 1940, and has been active in medical alumni association affairs for several years.

Loring, 55, specializes in obstetrics and gynecology. He received his M.D. degree from Stanford in 1946.

Election of the new officers of the 3,400 member association were announced during the annual alumni reunion over the weekend.

STANFORD--The National Labor Relations Board has upheld the firing of Sam Bridges, 23, by Stanford University Hospital.

After investigating the matter, the NLRB said Bridges was fired "for reasons related to his work performance."

The NLRB decision, rendered Tuesday (May 18), came in response to a charge filed April 7 on behalf of Bridges by the United Stanford Employees that he was unfairly dismissed.

USE charged that Stanford University Hospital "had interfered with, restrained and coerced and finally fired...Bridges in his exercise of the rights" guaranteed by the National Labor Relations Act.

Bridges, a Black hospital employee, was dismissed March 19 after a few weeks of employment at the hospital. His dismissal was cited as a reason for a demonstration early in April which resulted in some 28 arrests and a $100,000 damage at the hospital.

In letters to Jim Berk, president of United Stanford Employees, and to the Stanford hospital, NLRB Regional Director Roy O. Hoffman wrote:

"The investigation (conducted by NLRB) disclosed insufficient evidence to support the conclusion that Sam Bridges was discharged in violation of the act. Rather, it appears that he was terminated for reasons related to his work performance... It is concluded that further proceedings are not warranted. I am therefore refusing to issue complaint in this matter."

Hoffman said that under NLRB rules, USE may obtain a review of this action by filing an appeal with the NLRB general counsel in Washington.

The Stanford Daily Wednesday quoted Berk that USE plans to obtain a review of the NLRB action. The review would be requested on the grounds that the NLRB concentrated on the issue of the firing of Bridges to the exclusion of the lesser charges of interfering with, restraining, and coercing Bridges' union activities.

STANFORD--Stanford University Hospital will no longer routinely give out names of patients undergoing heart transplant operations.

Until recently the hospital released names when a heart transplant patient or his legal representative granted permission. It has done so routinely on nearly all operations performed at Stanford.

Dr. Eugene Dong, a member of the Stanford heart transplant team, Monday (May 17) explained the new policy: "In response to requests from patients and their families, and because of advances in heart transplantation, we no longer feel that our patients' names can be considered public information. They are entitled to as much privacy as other patients."

The hospital's most recent heart transplant--the 32nd at Stanford--was performed May 8 on a 46-year-old man. In keeping with the new policy, his name was not disclosed. The hospital has performed an average of one heart transplant operation a month since January.

There are now 12 surviving heart transplant patients in the Stanford program--two of them living more than two and a half years.

Stanford medical center spokesman Spyros Andreopoulos said the hospital would continue to report all the pertinent scientific developments in the field of heart transplantation in which there continues to be public interest. The hospital would also release statistics about the number of operations performed and survivors.

STANFORD--Dr. John A.D. Cooper, president of the Association of American Medical Colleges, will be the keynote speaker at the annual medical alumni reunion of the Stanford University School of Medicine Saturday (May 22).

Dr. Cooper, a biochemist and noted medical educator, will discuss the academic medical center and its role in improving the health of the nation at 1:30 p.m. in the Cooper Courtyard of the Medical School.

He will also talk about AAMC's viewpoints on the Carnegie Commission Report on Higher Education. The Carnegie Report calls for extensive reform of medical and dental education, development of nine new health science centers, and establishment of 126 "area health education centers" across the nation. It also proposes to reduce the time required to educate doctors and dentists.

After Dr. Cooper's talk, there will be a panel discussion on the Carnegie Report, moderated by Nobel Prize winning geneticist Joshua Lederberg in Room M-106.

Among the panelists will be Dr. Sherman Mellinkoff, dean of the UCLA School of Medicine; Dr. Roy Cohn, Stanford professor of surgery; Dr. Howard B. Kirtland of San Diego, president of the Stanford Medical Alumni Association; Dr. Bernard W. Nelson, associate dean of student affairs at Stanford medical school; Rodney L. Levine, a third-year medical student; and Dr. Cooper.

Morning sessions, beginning at 9:45 will feature clinical presentations on advances in the care of premature infants, medical genetics and prenatal diagnosis.

There will also be a presentation about the new human biology program at Stanford and its relationship to the medical school by Dr. Norman Kretchmer, professor and head of the Division of Developmental Biology and Laboratories.

Reunion dinners are scheduled in the evening.

STANFORD--Dr. David M. Kaplan, associate professor and head of the division of clinical social work at Stanford University School of Medicine, has received honorable mention by the American Psychiatric Association for outstanding research in psychiatry.

Dr. Kaplan received the honor for the book The Treatment of Families in Crisis, co-authored by Dr. Donald G. Langsley, professor and chairman of the department of psychiatry at the University of California, Davis.

The certificate of honorable mention was presented by the Hofheimer Prize Award Board of the APA at a recent meeting in Washington, D.C.

Drs. Langsley and Kaplan developed a program for family crisis treatment as an alternative to psychiatric hospitalization. Between 1964 and 1969, the project was carried out in Denver, Colorado, and later at UC, Davis.

The Hofheimer prize which honors outstanding research accomplishments in psychiatry this year went to Dr. Joseph J. Schildkraut of Harvard Medical School, and his associates for their work on the pathophysiology of affective disorders.

SPECIAL ANNOUNCEMENT
TO ALL HOSPITAL EMPLOYEES

The Medical Center News Bureau will serve as a rumor verification center for the Hospital effective immediately.

The purpose of this effort is to track down rumors throughout the Hospital and determine as much as possible if they are true or not.

Hospital employees concerned about a rumor should call Extensions 5311, 5312 or 5666 any time during the day. Calls will be logged on a data sheet and will be validated, confirmed or negated through local agencies, members of the Hospital administration, and minority representatives.

Rumor verification is being set up because of the tense situation that has prevailed in the Hospital over the incidents of the past few weeks. It is hoped that the new service will contribute to reducing tension and prevent incidents caused by false rumors.

Minority employees are urged to look for announcements of interest to them on the special bulletin board by the first floor escalator, and the News Bureau bulletin board on the ground floor adjacent to Room C003.

STANFORD--Dr. Peter D. Wood doesn't look or act the part of the athlete. The lean, balding, research associate at Stanford University School of Medicine wears glasses and distinctly has the appearance of the scholar. But looks can be deceiving. He is considered one of the finest senior distance runners in the country.

Wood, who has been running competitively since the age of six, was named the most outstanding senior runner in Northern California last year by a ballot of Amateur Athletic Union (AAU) runners. He is currently training for the annual Bay to Breakers race across San Francisco Sunday, May 23. Last year he finished 73rd in a field of over 1000 starters, and was first among senior (over 40) entrants.

This will be Wood's ninth straight Bay to Breakers, and to prepare for it the 41-year old lipid chemist from London will run between 50 and 60 miles per week. In the past, while training for the dozen marathon races he has entered, he has run up to 100 miles a week.

Why does he do it?

"Basically, I think I'm just a conceited old man," Wood smiles. "Every time some guy is killing himself to get to the tape, it's for conceit."

"There's some content of feeling it's good for you, but primarily it's the feeling of accomplishment, similar to climbing a mountain. When you climb a mountain, or run your fastest time, you feel terribly pleased."

Wood, a member of the U.S. senior track team which will travel to Europe next year to compete against English and German senior teams before and after the 1972 Olympic Games in Munich, has had a lot to be pleased about.

In 1964 he won the first annual 32-mile race from San Francisco to Stanford, and in 1968 he won a medal for his 35th place finish (out of 1000 starters) in the famous 26-mile Boston Marathon. For the past two years he has finished third and fourth in the Examiner All-American Indoor Games senior mile run at the Cow Palace in San Francisco.

"This is a great area to live in if you're a runner," says Wood. "If you reach 40 and you're moderately good, you have a chance to run in public meets before a big crowd. It's really quite exciting."

But Wood, by his own admission, would continue running even if there were no competition, no meets, and no crowds to cheer him on.

"I think if I were on a desert, with nobody there to impress at all, I'd still run very hard," he says. "There's a great deal of self-satisfaction involved. It's really a very personal thing."

Wood first felt the urge to compete in London in 1935, when a race for six year olds was held on the occasion of the Golden Jubilee of King George V and Queen Mary. -more-

"In those days it was important for every British boy to have his sport," he recalls. "Running wasn't popular then as it is now, but I managed to survive every urge to quit."

At 15, he was running a mile every day, despite warnings from a schoolmaster that "it is well known you will strain your heart."

Ironically, much of Wood's research is now concerned with reducing cholesterol and fat levels in the blood, which can often lead to heart disease. He often stresses the positive effects exercise can have.

"There are various connections between exercise and levels of cholesterol and fat in the blood," he says. "Exercise can help reduce these levels, and indirectly, may help lessen the chance of heart disease. Lower cholesterol and fat levels are associated with a lower incidence of heart disease."

He offers little hope to overweight joggers, however, when he says "Running is not really a very good way to lose weight rapidly. Actually, you'd have to run about 50 miles to lose a pound. What it can do pretty effectively is prevent weight-gain in middle age."

Apart from its physical values, Wood feels the emotional and psychological advantages of running are also important.

"Running is an escape from pressure, really," he says. "It's a substitute for your present problems, like worrying about the mortgage or something."

"Most of the time you're physically relaxed and emotionally strained, but in running, the reverse is true. You're physically strained, but emotionally and psychologically relaxed. It's so much work, you forget other things, most often the things that are bothering you."

With the 7.8 mile Bay to Breakers coming up soon, Wood has laid out a rugged training program for himself.

I'm going to try and train every day, if I can," he says. "Some days I'll run eight or nine miles in the Foothill College area. It's very pleasant up there and I'll take it slowly. Every other day I'll go to a track and run six miles at a fair pace."

A week prior to the race, he'll compete in a "warm-up" eight-mile run through Golden Gate Park.

This year's anticipated Bay to Breakers starting field of 1500 includes many women, partially due to Wood's successful campaign to secure "women's rights" in distance running events as president of Bay Area Road Runners Club in 1967. His strategy backfired on him recently, however, when he was beaten by a woman in a race at Walnut Creek.

"I was a little off color and she turned out to be a very good runner," Wood smiles. "You can't underestimate women. You've got to watch out for them."

STANFORD--Stanford University Hospital's blood bank has received formal accreditation by the American Association of Blood Banks.

In a letter to the Hospital the AABB said: "It has been determined that the level of technical and administrative performance within your blood bank meets or exceeds the standards established by this Association."

The Hospital's blood bank was opened in 1966, made possible by a $30,000 gift from the Hospital Auxiliary. The blood bank, one of only 43 in California and one of a few operated by a hospital, is equipped to draw blood from donors, type, process and store it in temperature-controlled refrigerators until it is needed for sick or injured patients.

In addition the Blood Bank now is able to divide whole blood into its various fractions for specific purposes. It is also testing each unit drawn for the viral hepatitis antigen to decrease the incidence of transfusion hepatitis.

Dr. Thomas A. Gonda, Hospital director, explained, "This certification is assurance to the p[illegible]c of the blood bank's continuing high standards."

###

STANFORD--Dr. Judith G. Pool, a senior scientist at the Stanford University School of Medicine, has been elected co-president of the Association of Women in Science (AWS).

She shares the AWS presidency with Dr. Neena P. Schwartz, professor of neuroendocrinology at the University of Illinois College of Medicine.

The association was organized recently by a group of women registered at the meeting of the Federation of American Societies for Experimental Biology in Chicago.

The purpose of this new organization is "to promote equal opportunities for women to enter the professions and to achieve their career goals," Dr. Pool explained.

An immediate aim of the new group is to prepare a North American registry of women in science, Dr. Pool said. This registry will be available to professional women seeking employment, and to employers seeking to fill academic or industrial positions. The group will also work to enlarge membership of women in scientific and professional societies.

Dr. Pool, a physiologist, is noted for developing techniques for obtaining the blood clotting factor needed for treatment of hemophiliacs. She has also been active in the Professional Women of Stanford University Medical Center. The group recently outlined proposals for increasing the number of women in medicine and in tenured positions on the medical faculty.

Further information on the new organization, may be obtained from the AWS treasurer Dr. Gertrude Schloer, assistant professor of microbiology at Mt. Sinai School of Medicine, City University of New York.

STANFORD -- Licensed vocational nurses at Stanford University Hospital will vote whether they wish to be represented by the California Licensed Vocational Nurses Association in collective bargaining in an election May 3, hospital director of personnel Kenneth Dunkle announced today.

The election, which will be supervised by the California State Conciliation Service, "will determine whether or not the organization will represent the Stanford LVN's in matters of wages, hours, and working conditions," Dunkle said. There are currently 51 LVN's at Stanford.

The election will be held in Room W001 by secret ballot from 6:30 to 7:30 a.m., and 1:30 to 3:30 p.m. on Monday, May 3. Notices will be posted throughout the Hospital for several days prior to the election.

The vote was scheduled after the CLVNA, claiming support from a majority of the LVN's at Stanford, wrote the Hospital asking for an election. Several Hospital nurses had contacted the organization and expressed interest in obtaining representation.

The last election of this type at Stanford Hospital was held March 30, 1967, when Hospital and Institutional Workers Union, Local 250, unsuccessfully attempted to organize all nonprofessional hospital workers. -30-

STANFORD -

Stanford University Hospital officials Tuesday, April 27, said they are prepared to resume meetings with "any group of employees on any Hospital-related issue."

Moreover, in such meetings hospital employees may have advisers present "within a framework of orderly discussions."

In a statement issued Tuesday night, Dr. Thomas A. Gonda, hospital director, said the hospital will "negotiate Hospital-related issues only with groups that can demonstrate they actually represent the employees who would be affected by agreements reached in the negotiations."

Dr. Gonda stated that the hospital does not recognize the "Stanford Medical Center Employees Coalition" as an appropriate bargaining unit nor their representatives as negotiators concerning terms and conditions of employment of hospital workers.

He added: "The Hospital administration looks forward to the establishment of a representative employee council with which it can consult on issues affecting the hospital employees.

"Only the widespread participation of all employees can ensure successful implementation of programs, including such vital programs as 'Affirmative Action.' "

STANFORD -- The Commonwealth Fund, a philanthropic foundation based in New York, has given a $505,686 grant to the Stanford University School of Medicine to support a University-wide program of research and education on the problems of human aggression and violence.

Announcement of the grant was made today (June 29) by Dr. John L. Wilson, acting dean of the School of Medicine.

The new program will be organized under the auspices of the Department of Psychiatry. It will be known as the Laboratory of Stress and Conflict. Dr. David A. Hamburg, professor and chairman of the Department of Psychiatry, will direct the program.

In a letter to Stanford concerning the grant, Quigg Newton, president of the Commonwealth Fund, wrote: "The Fund believes it is both appropriate and imperative for medical schools to concern themselves with the consequences to our society and civilization of the alarming rise in dominant, assertive, and violent behavior.

"Because, in its broadest sense medical learning is addressed to understanding the biological, psychological and sociological determinants of human functioning, medical schools are in a favorable position to take the initiative."

Newton added that such fields as education, law and government could also assist medicine "to forge a coherent, interdisciplinary attack on the underlying causes of aggression and violence and how they may be dealt with."

Hamburg, architect of the Stanford effort, said he hopes the program will be well developed in the next three years.

He envisions involvement of specialists from the biological, psychological, and social sciences, tackling research questions both at the basic science and clinical levels.

"Moreover, we hope to set up a curriculum on problems of violence and aggression that would provide a working model for other universities--both at the undergraduate level and in medical education," Hamburg said.

Space now occupied by the adult outpatient psychiatric clinics at the Medical Center will be vacated this summer when the clinics move to a new building. This space will be remodeled to house the biochemical and behavioral laboratories for the new program.

Hamburg also said he is developing a program of research and teaching in collaboration with Jan van Lawick-Goodall, a scientist noted for work on chimpanzee aggressive behavior at the Gombe Stream National Park in Tanzania since 1960.

In 1968, Drs. Goodall and Hamburg began planning joint research on aggressive behavior in nonhuman primates, both in Africa and at Stanford. Earlier this year Dr. Goodall served as a visiting professor at Stanford, and she is returning this fall.

-more-

Hamburg said animal studies are essential to obtain an evolutionary perspective "in which we perhaps can dimly perceive how man came to be the way he is, and search for subtle legacies of his ancient past."

He noted that "evidence is accumulating that begins to illuminate interactions of genes, hormones, and social environment in the shaping of aggressive behavior."

Other areas of research will include:

- Development of aggressive behavior in the early stages of life. This work will involve both animal and human studies of the role of early social environment for later social behavior.

- Problems of crowding, contact between strangers, and the psychobiology of modern living. This research will be concerned with relationships of population density to body chemistry and behavior.

- Stress and conflict in early adolescence. Some of the investigations will deal with the relationship of hormonal changes observed in puberty to behavior.

Hamburg commented that analyzing such problems scientifically holds much promise for future understanding of violent behavior. At present, the subject of aggression attracts only a modest amount of attention in the scientific community.

He said in research with pre-school children, "a remarkable set of findings has recently highlighted the susceptibility of children to learning aggressive patterns by viewing models who act aggressively."

The Stanford psychiatrist also commented that "biological predispositions to learning aggressive patterns and exposure to specific social learning situations may interact to produce great individual differences in aggressiveness during later life."

He said in light of present concerns about environmental problems, there is a remarkable lack of psychobiological research on the effects of crowding in man.

Concerning the studies of the adolescent, Hamburg said: "The prevalence of profoundly and pervasively hostile attitudes, the extraordinary spread of drugs, and the upsurge of violence in this age group sharply highlight the need for deeper understanding of adolescence."

STANFORD -- The School of Medical Technology at Stanford University Hospital graduated its fifth class of medical technologists Thursday evening, June 24.

A full year of training in the clinical laboratories and the classroom has readied the class of 12 for licensure by the State of California, and for certification by the Registry of the Medical Technologists of the American Society of Clinical Pathologists (ASCP).

The new technologists will work in laboratories in hospitals, clinics and medical research firms. Their specialized training includes instruction in 10 fields, with emphasis on biochemistry, hematology and microbiology. Miss Lisa von der Muehll is teaching supervisor.

Dr. Paul L. Wolf, director of the school, announced that the school has begun a minority recruitment program. The 12-member class which enters July 1 will include two minority students.

"This is a definite advance in our program," Wolf said. "We've never had a Latin-American or Black in our school before. Next year we hope to increase this number."

All entrants are required to have a bachelor's degree. In the past, most have majored in biology, chemistry, and microbiology.

The 1971 graduates are:

Miss Millie Ayres, a 1970 graduate of the University of California at Davis, daughter of Mrs. Helen Ayres, 4230 Silverado Trail, Napa, California.

Miss Julie Ann Foerster, a 1970 graduate of Stanford University, daughter of Dr. and Mrs. James Foerster, 3333 - 6th St., Wausau, Wisconsin.

Mrs. Carolyn Lee Hedrick, a 1964 graduate of the University of California at Berkeley, wife of Warren Hedrick, daughter of Mrs. Ruth Carmick, 440 Casita Way, Los Altos, California.

Miss Gerry Lynn Huffman, a 1970 graduate of University of California at Davis, daughter of Mr. and Mrs. Oscar Huffman, Route 3, Box 213, Orland, California.

Miss Michele Jungery, a 1970 graduate of University of Colorado, daughter of Dr. and Mrs. Wolf Jungery, 4704 Northwest 12th St., Oklahoma City, Oklahoma.

Miss Peggy Jane Ludwick, a 1970 graduate of Washington State University, daughter of Dr. and Mrs. Arthur Ludwick, 841 Red Apple Road, Wenatchee, Washington.

Mrs. Katie Parnell, a 1970 graduate of Utah State, wife of Gary Parnell, daughter of Mr. and Mrs. Kenneth Farrer, 1685 Saddle Hill, Logan, Utah.

Miss Alice Faye Ravi, a 1970 graduate of Michigan State University, daughter of Mr. and Mrs. William Ravi, 1710 Moorhouse, Ferndale, Michigan.

Miss Janice Eleanor Vierra, a 1970 graduate of California State College at Hayward, daughter of Mrs. Eugene Vierra, 20552 Forest Avenue, Castro Valley, California.

Miss Carol Ann Westlin, a 1970 graduate of Washington State University, daughter of Mr. and Mrs. Eric Westlin, 6551 23rd NE, Seattle, Washington.

Miss Janice Gail Young, a 1969 graduate of Beaver College (Glenside, Pa.), daughter of Dr. and Mrs. John Young, 3709 Cedar Drive, Baltimore, Maryland.

Miss Susie Chu-Hua Yu, a 1970 graduate of the University of California at Los Angeles, daughter of Mr. and Mrs. Hui-Sheng Yu, 1163 Sanborn Avenue, Los Angeles, California. ### Mailed 6/28/71.

It is an odd feeling for Verne Freeman who builds freeways, coaches the athletic teams of youth groups in Palo Alto and has seven children, to be in the hospital requiring the clotting factor of some 32 units of blood daily. He has already used up over 1,000 such units.

Verne is a hemophiliac, but usually he "forgets about it" since he does not require preventive treatement. His bleeding only starts when there has been an accident or an operation, and he has just had both. In fact he has had three operations to correct a severe knee injury that he got in an accident playing baseball.

He needs donations to make up the enormous quantity of blood that he still requires, but the point that he wants to emphasize is that no one really thinks about needing or giving blood until someone is in the hospital and must have it.

He hopes his case might be an example of the fact that blood should be available on a continuing basis for all of those who need it. "The appeal is really embarrassing--I've got so many friends who've helped so much already."

"Yet, the need for blood for others is always with us," he says.

Well known in the area, Verne is president of Freeman-Sondgroth Construction Company, and is active in the athletic programs at Stanford. He is a member of the Stanford Athletic Board, which helps advise on the direction of athletics at Stanford and is on the Buck Club Board, which is the fund raising arm of the athletic department at Stanford.

He is also president of Community Blood Reserve, a blood assurance program for families which provides whatever amount of blood needed in times of illness, accident of surgery.

For a $1 enrollment fee and an agreement for one family member to donate on call no more than one pint of blood once a year to the Stanford University Hospital Blood Bank, members in a family are covered if they have a need for blood, whether at Stanford or any other hospital. The few limitations under this coverage include hemophiliacs.

-more-

222--Verne Freeman

(The coverage does not pay charges associated with giving a transfusion, or crossmatching tests, which most health insurance plans cover, but works somewhat like a bank account--the blood given is insurance that it will be there for members and their families when it is needed, and at the same time will provide the community with fresh blood at all times.)

The CBR finance committee has recently approved a donation of $18,500 to Stanford University Hospital. The funds will help acquire new instrumentation and furniture for the blood donor and component facility to be built at the Children's Hospital at Stanford, which has become a major treatment center in the area for hemophiliacs. These monies will be available in the near future.

But Verne himself now has to replace around 400 units of whole blood to make up for all the blood that he is getting.

Dr. Judith Pool, a specialist in hemophilia at Stanford, who developed a simple method of extracting the substance needed by hemophiliacs--cyroprecipitate (cyro)--noted that the other blood components go to patients with different needs. "So any donation helps three other people."

"Blood giving should become a way of life," she says. "If the many families in this area gave blood on a continuing basis, there would always be enough."

For more information about the program, call the Stanford University Hospital 321-1200, extension 5979. It is sponsored by the Junior League of Palo Alto.

Blood donations can also be made, by appointment, with Stanford Blood Bank, Red Cross in San Jose, Peninsula Blood Bank, Burlingame, and Irwin Memorial Blood Bank in San Francisco.

Mailed, June 28, 1971

STANFORD UNIVERSITY NEWS SERVICE

STANFORD, CALIFORNIA
ZIP 94305.
(A/C 415) 321-2300, Ext. 2558

Following is the text of a statement issued Thursday, June 24, by Robert Nelson, Stanford University director of personnel and employee relations, concerning the dismissal of five University employees:

In discharging five employees for participation in the occupation of the administrative offices of the Stanford Hospital on April 9, 1971, the University was not acting as a law enforcement agency but as an employer making judgments about conduct which it deemed unacceptable on the part of the employees. This distinction is central to any attempt to understand the issues involved. To put the matter even more sharply, the University has not charged any of these employees with committing a crime, nor has it alleged that the conduct which serves as the basis for dismissal constitutes a crime. The five persons involved have not been dismissed because of any allegations that any of them committed trespass, assaulted a police officer, or engaged in any other criminal act. Nor is the asserted political content of their acts at issue. They have been dismissed simply and solely for participating in the occupation of the administrative offices of the Stanford University Hospital on April 9, 1971, and which in the University's judgment, makes these persons unsuitable for further employment in the University.

It is important to understand this point because it is easy to be misled into thinking that this employment action is simply another statement of criminal charges already pending against these individuals. It is not. The two overlap only in the sense that the same set of events produced conduct which the State believes chargeable under criminal statues, and conduct which demonstrated unsuitability for continued employment at Stanford. These were separate actions based on independent inquiries taken in discharge of different responsibilities.

I have made this point at some length in order to shed light on the demand that the University delay its proceedings until criminal charges are disposed of in order that the former not "jeopardize" an individual's defense against the latter. The University's unwillingness to delay action on employees whose conduct it deems unacceptable until the criminal courts have completed action on a different set of charges is consistent with well established practice in a variety of circumstances in the law. Far from being an unusual act, it follows the general rule in cases where cirminal and civil actions result from a single set of events. To argue otherwise is to say that no private party can remedy a wrong against it in a timely manner if the wrong is alleged by the State to involve criminal conduct or, indeed, if the individual who committed the act believes that answering for it might make him liable to criminal charges. That is an untenable position.

Each of these individuals was offered the opportunity to respond to the evidence, and provide any additional information that would bear on this case.

The five persons involved have been advised in writing that they are entitled to a hearing if they believe that they have been treated improperly or unfairly. In that hearing they may challenge the evidence on which the action against them is based, as well as the interpretation of University policy on which it rests. That is their proper course of action if they believe that they have been unfairly treated. —30—

Following is a statement from Provost William F. Miller concerning his meeting with Medical School faculty members, Thursday, June 24:

I met today with Profs. Herzenberg, Holman, McDevitt, Rosenberg, and Goldstein. We spoke entirely about the procedural aspects of the cases of the dismissals of the five staff employees for their participation in the hospital disruption of April 9.

We did not talk about the merits of the cases because I shall very likely be involved in a review of some of the cases at a later date. I have determined that the procedures employed were consistent with our policy, and that they are adequate for these cases.

All department chairmen were consulted and advised before actions were taken.

City Desks: This side bar to main story describes one patient care program at the Palo Alto VA Hospital, and how it could benefit community patients.

STANFORD -- Under a federal law, passed two years ago, veterans' hospitals can now share their facilities with medical schools for the benefit of community patients on a space-available basis.

Here is how the new law works for one program at the Palo Alto Veterans Administration Hospital designed for stroke victims.

For such patients the referring agency or doctor only needs to contact the physician-in-charge of the stroke program at the VA Hospital.

The patient's eligibility is determined by the business office of Stanford University Hospital, which acts as fiscal intermediary. The VA Hospital presently does not bill directly.

After securing the necessary information about the patient's insurance (private or Medi -Cal), the patient's family is given an opportunity to visit the hospital in advance to inspect the facilities.

The tour for the stroke program is conducted personally by a full-time faculty member in the department of neurology (it might be cardiology or surgery for another type of patient), and questions are answered.

The family is introduced to the nurses who will care for the patient, and if the patient is a woman, she is shown one of the single rooms, along with the private bath facilities.

Admission to the coordinated-care-stroke program means that, in addition to the house officer primarily responsible for the patient's day-to-day care, a team of other specialists are called in. They are all on the full-time staff, and most are also faculty members of the Stanford Medical School.

In the initial phase of the program, a neurologist, a psychiatrist, a public health nurse, and social worker see the patient within the first few days.

Contacts are established with the referring doctor and the family, no matter where they may be. The diagnostic studies go ahead under the supervision of the full-time faculty neurologist who is responsible for the program, and consultations are obtained at no extra cost to the patient, the state, or the insurance company from other specialists.

-more-

The patient's progress is closely followed daily by the nurse coordinator, and the entire team meets every other week to plan for the next phases of care.

In the second phase, when the patient is no longer bed-bound, he and the family are involved in planning for follow-up rehabilitation efforts and posthospital care.

At the same time, if psychological problems have appeared, a full-time psychologist or psychiatrist makes his service available (daily if needed) to the patient and his family.

Meanwhile, if the family is willing, a home visit is made by the public health nurse on the team, and provisions are made for any modifications or adaptive equipment that will permit the patient to go home.

If the VA public health nurse cannot travel to the patient's home community, the county public health nurse is asked to make the home visit and make recommendations to the VA hospital team.

Similar arrangements are made for speech therapy and other training after the patient leaves the hospital.

Before discharge, the patient's doctor is contacted by phone, and the findings and treatment are discussed. The ward nurse is also instructed to have a question and answer session for each patient and his family prior to dismissal.

"In this way," says Dr. William W. Hofmann, chief of the Palo Alto VA Hospital neurology service, "the VA team interacts with many facets of the community.

"The patient is given an opportunity to see many specialists about his problem without incurring large debts for doctor fees while in the acute inpatient services of his illness, and the patient is fully informed about the practical aspects of his condition."

"Exactly the same coordinated care is given to all veteran patients," Hofmann explains, "and we feel that the approach has considerably reduced the feeling of depersonalization many patients experience in a busy, large institution."

Most important, adds Hofmann, "for anything from intensive care to a 16-bed ward management the cost to the state or commercial carrier has been from one-third to one-half what it would have been elsewhere."

Science Writers: Photos available upon request.

STANFORD -- A Stanford University neurology professor says that hundreds of beds in veterans hospitals are empty in spite of a federal law encouraging public use of VA hospitals.

Among them is the Palo Alto Veterans Administration Hospital where "one can always find several hundred empty beds not required by veterans," said Dr. William W. Hofmann, chief of neurology there.

"The VA medical system ceased to be for veterans only, when public law 89-785 was passed," said Hofmann.

"For over two years now the means have been at hand to utilize VA beds for specific medical, surgical and rehabilitative programs for community patients," he said.

Hofmann said Congress correctly decided that the largest federal medical system in the world could well share some of its facilities with communities and medical schools. Several Stanford medical school departments now take advantage of this decision through "sharing" contracts which permit admission of community patients to the VA.

Yet few doctors have seen fit to refer patients to the VA, Hofmann said. And no effort has so far been made by local comprehensive health planning agencies to incorporate this huge tax-supported system into regional or community health planning.

"If the Congress has made it possible for the VA system to interact with communities," he continued, "how can the counties and cities overlook the hundreds of available beds right under their noses?"

Hofmann said an evaluation of university-affiliated VA hospitals as part of the total community's resources is long overdue.

"It is inappropriate," he commented, "to ask taxpayers to pay more in support of a sagging, overburdened local health care system when they have not been presented with an opportunity to use a first class operation already paid for with federal taxes."

Hofmann presented his views in an article in Stanford M.D., the magazine of the Stanford Medical Alumni Association, scheduled for publication next week.

He acknowledged there is public resistance to the VA system, "largely colored by inflammatory articles in recent popular magazines."

But if a study group elected to visit one of the university-affiliated VA hospitals, it would form a different opinion, Hofmann said.

Such VA hospitals, he argued, are staffed by physicians whose credentials entitle them to teach medical students and resident doctors, and to hold faculty positions at a university.

They include every major and minor specialty (except pediatrics and obstetrics), and the equipment is the best physicians can procure--namely, the equivalent of that in any other major hospital, he said.

-more-

In addition, paramedical personnel unequalled in any private hospital is available, and patient-oriented and basic research are in progress.

Although a "sharing" arrangement with an approved VA hospital might be the ideal approach to treat community patients who may be waiting unnecessarily for care, doctors have tended to express contempt for the VA medical system, Hofmann said.

Veterans' organizations "have also been actively concerned and hostile" to the sharing plan, according to the Stanford neurologist.

He said veterans insist on one hand, "for the best care for our boys," and on the other, that VA hospitals become nursing homes admitting every veteran who applies, whether he needs medical care or not.

"No custodial VA facility is going to attract the highest quality trainees and staff," Hofmann said. "The medical needs of the veteran patient are never going to be fully met in a nursing home atmosphere, which will be the most expensive in the world."

Hofmann stressed taxpayers can get an even break only if the VA system is put to its fullest use, with active patient turnover and strong interaction with the service needs of the entire community.

"Only then the veteran patient can get the good care to which he is entitled," he said.

At present several services headed by Stanford faculty at Palo Alto VA Hospital have sharing agreements to admit community patients referred by local doctors.

Community patients may be admitted if they need a service not presently available in their community, and when the VA hospital has such a service not needed by veteran patients. The patient must also be supported by his county or some form of health insurance.

Hofmann pointed out that the VA charges about $45 a day--roughly half the minimum basic cost of a bed in a local community hospital. This amount covers all routine procedures, and as with veteran patients, no doctor's bill is sent.

"If a community had no free beds, a tremendous saving to local taxpayers could be realized just by using VA facilities in which there would be no physician's charges," he said.

Hofmann stressed that VA physicians who run training programs and are part of the academic faculty are no longer willing to let their beds fill up with custodial patients, and hang a "no vacancy" sign.

"Instead, we are asking for more work and involvement in the community as a whole," he said. We challenge the health planners to provide us with a flow of patients who may be waiting unnecessarily for care and advice.

"If we fail in this, it will only be because we haven't been given a chance."

FOR IMMEDIATE RELEASE
STANFORD –

Several faculty members at Stanford University met with Provost William Miller Thursday, June 24, to ask for the reinstatement of five employees fired earlier this week for allegedly taking part in a sit-in at the University Hospital April 9.

Following the one-hour meeting with Miller, representatives of the faculty group held a press conference at noon, and threatened to take legal action if the employees are not reinstated.

In a statement released to the press, professor of genetics Leonard A. Herzenberg, professor of pharmacology Avram Goldstein, and Dr. Halsted Holman, chairman of the Department of Medicine, said:

"We urge the immediate reinstatement of these employees at least until after their court trials, [when they could] properly respond to University charges without ceding First and Fifth Amendment rights."

Herzenberg said that Provost Miller has promised to answer this request by 5:00 p.m. Friday.

At the press conference, Goldstein and Herzenberg both expressed concern that faculty members carrying out valuable research would have their work jeopardized by the sudden firing of employees for activities "not connected with their work performance."

"We are prepared to take legal action against the University to prevent this," Goldstein said.

"The rights of faculty members—particularly principal investigators—must be considered here," he said. "If my employee can suddenly be fired out from under me, this can be an irreperable loss."

Goldstein stressed that researchers feel a responsibility to funding agencies, and that the University is "disrupting" the close relationship between faculty members and the organizations supporting their research.

The five fired employees, dismissed June 22 for "unacceptable behavior," are Anthony Chatmon, clinic employee at Stanford; John Dolly, genetics lab assistant; library worker John Keilch; biology research assistant Mrs. Barbara Mooney; and Law School secretary Devera Satisky.

Dolly works under Herzenberg in researching the genetics of mammalian cells.

"The firing of an employee involved in research. . .without the consultation of the principal investigator is unacceptable," said Herzenberg, who claimed he was informed of Dolly's dismissal with only 27 hours notice.

"My research has been jeopardized," he went on. "The civil authority is adequate redress for the University. . .I don't think an institution should be able to fire an employee if there is adequate civil authority involved in the case."

Holman pointed out that University students charged with misdemeanors because of their alleged involvement in the sit-in will not have a University hearing until after their court cases, while the five fired employees were not granted this extension. They were offered a hearing with Personnel Director Robert M. Nelson before their firing, but turned it down for fear of jeopardizing their court cases, Holman said.

"There is a discrepancy here," he said. "The employees are put in the position of either jeopardizing their position in court, or losing their jobs at the University."

Other faculty members who have expressed opposition to the firings include Dr. Leon Rosenberg, associate professor of medical microbiology; Dr. Hugh O. McDevitt, associate professor of medicine; Dr. Luigi Luzzatti, associate professor of pediatrics; and W. Bliss Carnoch an associate professor of English.

"If people who commit such acts are to be fired in this way by the University," Rosenberg said, "it suggests that we'll be forced to hire people according to criteria which are irrelevant, such as political activities. . . . This is the kind of climate that existed in the McCarthy period."

Keilch, who appeared at the press conference with Dolly, Mooney and Satisky, indicated that the five employees had been planning to request a grievance procedure, but now feel that "we don't know if there'll be any point to it."

STANFORD -- When a rural town suddenly finds itself without a doctor--and no new doctor seems willing to take his place--what can the town do?

Most such communities find they can do very little, but that is not true for Livingston, Calif.

In a short time, the little town (pop. 3,000) has converted itself from a community in grave need into a model that may hold some meaning for all other communities lacking health care.

Livingston now operates a community-owned, self-supporting and locally-directed health center, with consulting specialists.

The center, known as the Livingston Community Health Services, is backed up by the Stanford University School of Medicine.

According to Dr. Everett Johnson, the center's medical director, health services are now available in Livingston that are usually enjoyed by communities of 50,000.

"The organization and style of operation are the innovations," says Dr. Count Gibson, Stanford professor of community health and preventive medicine. "The whole set-up is a far cry from a bureaucracy, or distant imposed restrictions.

"The local board sets up the program, identifies its priorities and pinpoints the available resources--whether through a university or elsewhere--to help bring its own plans about."

Dr. Gibson adds another dimension to the picture of the Stanford-Livingston cooperation. "It is the kind of partnership (with a community) that university medical centers have not thought of achieving in the past," he says.

Among critical problems Livingston has tackled, in addition to the short supply of rural physicians, are the spiralling cost of health care, the scarcity of government funds, and the frequent inability or unwillingness of medical schools to exercise new leadership and direction.

Livingston's health care enterprise began when the town's only doctor announced he would leave by fall, 1970. For Stanford, the tie to Livingston was made when a group of medical students went there in the summer of 1969 to conduct a clinic for migrant workers.

This effort has now evolved into a full-fledged partnership with Livingston offering health services for everybody. Stanford's department of community and preventive medicine sponsors the project.

But the community-run aspect of the health center and the community-set goals are both a major reason for the success and a continuing part of the story, Gibson comments.

Community diversity has also to be reckoned with. In Livingston, one of the string of little towns off Route 99 in San Joaquin Valley, live Mexican-Americans, Portuguese-Americans, Japanese-Americans, Filipinos, descendants of pioneer settlers and a large Mennonite community--all native Californians and many native to Livingston itself.

-more-

Four basic principles guide the health center:

It is community controlled and through a local governing board, consumers decide what programs they want and what they can afford.

Reflecting this is the involvement of the Mennonite community. Their religion prevents them from serving on any governing body, but they have been staunch supporters of the health center through work on committees. Also, the Mennonites have long taken a naturalistic approach to medicine and prefer to have children born without intensive use of anesthetics or medication.

Currently, prenatal health classes go on at the center, open to expectant mothers and fathers, led by a woman with nursing background from the Mennonite group. Regular obstetrical care and techniques of natural childbirth are taught.

The health center is self-supporting.

Livingston residents felt that dependence on sources beyond their community might lead to a loss of local responsibility. They believed also that uncertainty of funding or policy might develop if the community looked for outside help. Consequently, no federal funds were sought.

While there is agreement that there are sufficient local dollars to get the center operating, it could not go it entirely alone, Gibson points out. In fact, it will be operating at about the top of its capacity during the coming year.

Dr. Gibson also notes that center finances are compatible with current proposals before Congress regarding national health insurance. In other words, if some sort of national health program (with adequate safeguards to insure that the money would be spent wisely) went into effect, it would serve as a much needed component to Livingston's own capacity to give its citizens adequate health protection.

The health center serves a geographically defined population.

"Livingston is an ideal size for such a center," Dr. Gibson observes. "But to insure that the people who control the center will continue to be served by it, it should not expand much more."

Otherwise, Dr. Gibson fears all gains might well be lost through bigness and depersonalization.

One of the corollary interests of Stanford in Livingston is to determine if the health care model established there is repeatable. The Department of Health, Education and Welfare has given Stanford a small grant to study Livingston's approach.

The center is operated to serve the entire community.

According to a center document, "This reflects the community's desire to avoid the traditional pattern of one quality of care for the rich, another for the poor."

The center is organized as a nonprofit corporation guided by a board representing a broad spectrum of the community. The 19 organizations in Livingston, including the ethnic groups, United Farm Workers, Chamber of Commerce, high school student body, and senior citizens club, each have elected a representative. There are also 10 "at large" positions to insure that people living in the outlying districts participate.

The board forms working committees to deal concretely with specific issues, such as fee schedules, grievances and finances. Community members may also be invited to serve on these working committees, which are each chaired by a board member.

Currently, according to Fred Kishi, board chairman, more than 100 Livingston residents are directly involved.

To help the center get started, the California Regional Medical Programs gave a small planning grant. The local elected board set out on a drive to raise an additional sum to buy the offices of Livingston's retired physician, which already constituted a small working clinic. With extensive community involvement, the money was raised.

-more-

Last September, Dr. Johnson, an internist from the area, was persuaded to come on as health center director. As a further enticement, he was given a Stanford medical school teaching appointment.

Dr. Johnson points out he made a real sacrifice as far as income was concerned. His entire salary is paid by the center. But both he and his wife think that if American medicine is going to continue to advance, doctors themselves must take the initiative in providing a new approach to health care for the communities that need it.

He believes that because he is an internist, the diagnostic problems can be handled faster, which in itself reduces patient costs and perhaps shortens the time of illness.

Assistants for Dr. Johnson have also been found, and through them, the health center hopes to show that a doctor's efficiency can be increased.

As part of their medical school education, Stanford students have an opportunity to learn what all-around medical practice is really like by coming to Livingston. In addition, Stanford resident doctors rotate there throughout the year as part of their training.

The staff at Livingston also includes a full-time nurse practitioner. She is a recent graduate of a pilot Stanford program which prepares registered nurses to aid doctors in providing care for the entire family. In essence, the program gives nurses additional knowledge that will let them act as "physician-extenders."

The nurses are trained to identify what they can appropriately handle and when the doctor must be reached immediately. (Is it appendicitis, or a bad case of flu?) In any case, the nurse can go ahead with the preliminary findings, order the lab work done, describe the urgency to the doctor, and deal with the problem at hand.

Mrs. Lois Sykes, Livingston's nurse practitioner, says at first she was afraid she would not be accepted by the patients, but an associate comments: "Patients are now coming in asking for Lois and are disappointed if she does not see them."

For the second year, Stanford fifth-year nursing students will also be at the health center this summer. The aim is to help Mrs. Sykes and the other nurses, and also to get them involved as community aides in plans that are projected for migrant workers.

During the coming months, the health center is expected to get a full-time pediatrician. His arrival is eagerly awaited by the Livingston community, as there has been no pediatrician at all in a hundred-mile radius.

New plans under way for the center include an outreach education program to prevent injuries or accidents, and a program to give farm workers immediate treatment and education in the proper techniques of handling toxic sprays. Other efforts include family planning information, home nursing services, treatment of the chronically ill, and increased emphasis on the health of school children, as well as better maternity and infant care.

Are there any lessons to be learned from Livingston?

"The Livingston approach is community enterprise at its best," Dr. Gibson comments. "It offers a competitive challenge for doctors and hospitals to do better in their own delivery of health care, or they will be equalled by the strength of the community-oriented centers which are coming on strong."

STANFORD -- Stanford University Hospital Monday (June 21) announced it will admit podiatrists to its medical staff.

The move to grant these health professionals staff privileges was recommended by the Hospital's medical board, and has been approved by the Hospital directors.

Until recently Stanford Hospital bylaws had no provision for including podiatrists on the staff.

"The change reflects the new role podiatry is assuming as a needed dimension in medical care," said Dr. Thomas A. Gonda, hospital director.

Presently, the department of dermatology has a podiatrist on its staff who teaches medical students, residents, and participates in patient care, Dr. Gonda said.

The department of community and preventive medicine also sees podiatrists as an essential part of the comprehensive health care delivery system.

A podiatrist is a non-M.D. who specializes in diseases of the feet. Podiatrists are highly trained professionals who attend four-year postgraduate colleges, and must meet minimum undergraduate requirements identical to those for medical school. Recently, a rapidly growing number of podiatry graduates have begun to serve formal internships and even residencies.

There are nearly 8,000 podiatrists in the United States, and five postgraduate podiatry colleges graduating about 250 foot specialists a year. One of the colleges is located in San Francisco.

Because podiatrists do not hold M.D. degrees, but make independent judgments in diagnosis and treatment, their proper role in health care had been controversial.

In recent years, however, changing attitudes about health care organization have allowed podiatry to win increasing acceptance as a division of the healing arts.

STANFORD--An increase in daily room rates beginning July 1 was announced today by Stanford University Hospital.

For area residents the daily room rates will now be $64.50 for medical and surgical wards. Semi-private rooms will be $70.50 and private rooms $79.50.

Obstetrical ward rooms will now be $66 daily, with nursery rooms at $46. Coronary care units will be $184 daily.

This represents an overall increase of about four dollars. A year ago there was a flat $5.50 increase in daily rates, and the year before there had to be a $7.50 increase.

"The continuing rise in the cost of wages for personnel and materials has given us no option except to make this new small increase in our operating revenues," said Dr. Thomas A. Gonda, director of the hospital.

"However, we are doing everything we can to slow the hospital cost spiral," Gonda continued. "The cost of health care is as much concern to the hospital administrators throughout the nation as it is to the patient. At Stanford a number of administrative and operating innovations are already in effect which help us keep costs in control as best we can without sacrificing quality care."

STANFORD -- "The Palo Alto area is one of the biggest middle class junkie scenes in the United States today, but doctors here are hardly aware of the problem or refuse to deal with it," the founder and medical director of the Haight-Ashbury Free Medical Clinic said Friday (June 18).

Dr. David E. Smith charged that doctors in general are among the least informed about the illegal drug traffic that is going on, and treatment of addicts is rarely taken into consideration as part of the health care delivery system.

Yet 500,000 addicts are now seen and treated in the drug clinics springing up across the country, he said.

Dr. Smith is also assistant clinical professor of toxicology at the University of California, San Francisco. He spoke at the Annual Faber Day Symposium at Children's Hospital at Stanford.

"Heroin is the in-group drug to take in 1971," he said. "Heroin and its treatment should be one of the hottest items in the country right now--and an enlightened approach to treating its users is crucial."

"The new-style junkies are from middle class families, and these families are devastated when they find out the truth about their children. They need as much help as do the addicts," Smith said.

"There must be an interaction between counseling and education from the earliest years on. It must be a question of attitudes from the very beginning. It is too late to tell a teenager not to use dope, when he has grown up seeing the liquor and cigarettes used by his parents. Intensification of a human ecology approach in the early years as against a moral or wrong-doing attitude later on is the only way that shows promise of success," Smith continued.

"However, no drug education or control program will be totally effective until the Vietnam war is ended," Smith said. "A whole new generation of addicts has been created by this war, and their number exceeds the casualties.

"We have an obligation to treat these addicts as disabled veterans, not as criminals or those with a history of drug abuse or emotional ills before they went to war.

"The American public would be duped if it believes these current Pentagon charges, and supported the proposal to set up detention camps for veteran addicts who are returning to this country. We must resist a political whitewash," Smith urged. ###

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Gary Cavalli 415: 321-5310

STANFORD -- A broadened work-study program has been launched at Stanford University Hospital to qualify and train interested employees for job advancement within the Hospital.

The program was announced in the Medical Center's monthly newsletter, which was distributed to employees Monday, June 21.

The program offers classroom education for employees who desire instruction in English or wish to pass the California General Educational Development test (equivalent to a high school diploma), plus on-the-job training to prepare employees for specific jobs within the Hospital.

"Basically, this is a reorganization and broadening of previous education and training courses," said Dr. Thomas A. Gonda, hospital director. "It brings together elements of these earlier, episodic programs, coordinates them into a unified whole, and builds on them. This consolidated program is more suited to the needs of the hospital, as well as of the individual employees of the hospital."

Tony Rodriguez, originally appointed director of Latin Resources at the Hospital April 1, is the director of the work-study program.

"The basic concept we started from," Rodriguez said, "is that what's good for the minority employee is most likely good for all employees of the hospital.

"Our major interest is not in creating jobs, but in creating careers," he said. "The traditional barriers for minorities and whites on the bottom rung of the economic ladder have been lack of education and training. We believe that with the proper incentive, motivation and counseling, we can overcome these barriers."

In the case of the work-study program, the special incentive and motivation is threefold: the schooling, for the most part, will be conducted on the Hospital premises; the employee will in most cases be paid for the time he spends in class, so he won't lose money by going to school; and he'll be trained for a specific job in the Hospital.

"All these factors will make the employee more productive, increase his sense of worthwhileness, and stabilize him as an employee," Rodriguez said.

"To the best of my knowledge, this is the only program of its kind in a hospital west of Chicago," he noted.

The Hospital will provide major resources to run the program, Gonda said, including training personnel and hospital facilities. "In time, the Palo Alto Adult Education Program and local junior colleges will hopefully play an increasing role," he added.

Employees at the Hospital will have the opportunity to enter the program at any of the various levels--conversational English, GED, or job training.

The work-study program is expected to train employees for work in four areas at the Hospital--nursing, clerical, science and engineering. The emphasis will be on filling specific job openings in each department.

-more-

"All our classes will be tailored to meet the specific needs of the Hospital," Rodriguez said, "so we'll be producing our own highly-trained labor force. In general, no employee will enter a class without first having a job committed to him."

Before moving on to the advanced training phase of the program, many employees will have the opportunity to take conversational English courses, or finish high school by fulfilling the California General Educational Development (GED) requirements.

The six-week English courses were initiated at the Hospital June 9, with an opening enrollment of 30 employees, grouped in six classes according to skill levels. Each employee attends class for one hour per day with pay. "Class times and individual scheduling have been set with the intent of inconveniencing the departments involved as little as possible," Rodriguez noted.

Instructors for the English classes, recommended by the Stanford Linguistics Department, are Mitchell Hall and Kathleen Colyer, both of whom have teaching experience in English. Hall taught English as a second language for the Peace Corps in Africa.

"The basic teaching technique we're using is a psycho-social approach to linguistics," Rodriguez said. "Our teachers are attuned to the cultural needs of adults who are learning English as a second language. The course is offered to all interested, so this involves not only Spanish, but Filipino and European employees as well."

The GED phase of the program hopes to utilize the personnel and facilities of Stanford, Palo Alto Adult Education and local junior colleges. "Stanford University minority students have already volunteered their services as tutors in the English and GED programs," Rodriguez noted.

The GED program is due to begin July 15, while the individual training programs have a target date of September 1.

"We'll wait until September to give ourselves a chance to get better organized, and also to possibly obtain federal funding, as well as more institutional help," Rodriguez said. "Also, we want to give our first graduating classes of conversational English and GED the opportunity to get into the more advanced classes."

Hospital officials hope that eventually as many employees as possible will take part in the program, although initially classes are expected to be small.

"While we're getting off the ground, our classes will be very small," Rodriguez said. "Selection will be based on potential and need. But eventually we hope to open the the program up to all interested employees, with order of selection on a need basis."

Applicants for all job training programs will be counseled and directed to the fields for which they are best suited.

"Counseling will be very important," Rodriguez said. "We want to make sure each employee is channeled to the job where he'll have the greatest chance of success. Additionally, no one can 'flunk out' of this school. Anyone having difficulty will be transferred to another area, more suitable to that individual."

STANFORD -- Dr. John L. Wilson, acting dean and executive officer of the Stanford University Medical Center, did not receive the Henry J. Kaiser Award for excellence in teaching at the annual convocation of the Stanford School of Medicine June 13, as was reported in a release of June 14.

Rather, Dr. Wilson presented the awards to the four winners of the Kaiser Awards, who were Dr. Allen B. Barbour, M.D., associate professor of clinical medicine and head of the division of ambulatory medicine; Dr. A. Kent Christensen, Ph.D., associate professor of anatomy; Dr. Eugene D. Robin, M.D., professor of medicine (respiratory) and physiology; and Dr. Paul L. Wolf, associate professor of pathology.

The Medical Center News Bureau regrets the error.

STANFORD -- Dr. Paul Gyorgy, well-known authority in the field of childhood development and nutrition, today voiced strong support for breast feeding of infants as "absolutely the best thing that babies can have."

The Hungarian-born pediatrician made his plea for a "renaissance in breast feeding" at the seventh annual Harold K. Faber Clinical Symposium at Children's Hospital at Stanford. The overall topic of the symposium is "The Child and the Changing Environment."

"Breast feeding is rapidly disappearing in highly developed countries," said Gyorgy, emeritus professor of pediatrics at Philadelphia General Hospital. "In the northeastern part of the United States, at least, 80 per cent of babies leaving hospitals are already on cow's milk."

"Human milk is for humans, and cow's milk is for cows," Gyorgy said.

He cited new scientific research which showed that infant mortality is markedly decreased among babies fed human milk. In fact, he stressed, a baby fed breast milk and no solid foods for the first three months of his life will be much more healthy than one fed cow's milk and solids.

"Fat cells in the body are produced during the first six months and remain with us for the rest of our life," he said. "Often there is nothing we can do to get rid of them." He emphasized that human milk, containing less fat-producing agents than cow's milk, is "exactly what the growing baby needs."

STANFORD -- Dr. David A. Prince has been appointed Chairman of the Department of Neurology at Stanford University School of Medicine, Dr. John L. Wilson, acting dean, announced today (June 17).

Prince, acting chairman of the department since last October, was simultaneously promoted to professor of neurology.

Neurology was a division of the Department of Medicine until last fall, when it was established as a separate department at the School of Medicine. This change pointed up the growth of neurology as a separate discipline, and reflected the increase in clinical and neurological research activities at Stanford and elsewhere.

Prince, 38, received his M.D. in 1956 from the University of Pennsylvania and his training in clinical neurology at the Mt. Sinai Hospital in New York City. He has been at Stanford since 1962.

His major research interests are in neurophysiology and experimental epilepsy. Earlier this year he was named as a recipient of the 1971 John Simon Guggenheim Memorial Foundation Awards, for his contributions in research of abnormalities of single nerve cells in epilepsy.

STANFORD -- Frank R. Vitale, deputy director of Stanford University Hospital, has resigned to accept a partnership with Herman Smith Associates, a national hospital consulting firm.

His appointment as a principal partner becomes effective on July 1.

Founded by doctors 27 years ago, Herman Smith Associates has built nearly 500 hospitals across the country. Vitale has been an advisor to the firm for over two years.

"I feel my experience here at the Hospital has been an extremely rewarding one," he said, "but the offer of a partnership in this long-established firm is one that doesn't come along every day. It would be only this type of opportunity that would lead me to such a decision at this time."

The firm is headquartered in Hinsdale, Illinois, with offices in Newport Beach, California, and Palo Alto. Vitale will be in charge of the Palo Alto office.

A specialist in medical facilities planning, engineering, and management, he came to Stanford in 1961 as chief engineer. He soon advanced to management associate, assistant director, and associate director of the Hospital. In January of this year, he was appointed deputy director.

Vitale, 42, graduated from the U.S. Merchant Marine Academy in 1949 with a B.S. degree in mechanical engineering. He became a licensed chief engineer in 1955.

He is married, has two children, and resides in Menlo Park.

His professional affiliations include membership in the American Hospital Association and the American College of Hospital Administrators. He is past president of the National Association of Power Engineers (Peninsula Chapter) and currently president of the Kings Point Alumni Association, San Jose Chapter.

(ADVANCE) FOR PM RELEASE FRIDAY, JUNE 18, 1971

STANFORD -- Dr. Norman Kretchmer has been named first Harold K. Faber professor of pediatrics at Stanford University School of Medicine.

Dr. Kretchmer, who has won many honors and awards for his work in pediatric research, has been professor and executive head of the department of pediatrics at Stanford.

He returned to full-time teaching and research in 1969 after ten years as chairman of the department. He currently heads the division of developmental biology and was active in setting up the new interdepartmental human biology program offered to Stanford undergraduates.

The Harold K. Faber chair at Stanford was established a year ago in honor of Dr. Faber of San Francisco, emeritus professor and head of the department of pediatrics at Stanford for 26 years before his retirement in 1949.

Dr. Faber is internationally known for his polio research. He is a former president of the American Pediatric Society and received the Society's Howland Medal and Award in 1956 for his extensive contribution to his profession.

"The appointment of Dr. Kretchmer to fill this chair is a particularly happy choice. Dr. Kretchmer's outstanding record serves, in a sense, as a continuation of the tradition of Dr. Faber," said Dr. John L. Wilson, acting dean of the School of Medicine at Stanford.

Dr. Kretchmer's classes in pediatrics and human development at the Medical School have long been sought after by students.

In 1969 he received the Borden award of the American Academy of Pediatrics for outstanding achievement in research relating to nutrition in the development of infants and children. He was specifically honored for a study leading to the understanding of biochemical processes which form the basis of the distinctive cell differentiation in growth and development.

Formal announcement of the appointment was Friday (June 18) at the 7th Annual Faber Day Symposium at Children's Hospital at Stanford. The overall topic was "The Child and the Changing Environment." Dr. Kretchmer delivered the Faber lecture, entitled "Growth and Adaptation."

FOR IMMEDIATE RELEASE

STANFORD -- A method for studying a key biochemical process in protein synthesis has been developed by a Stanford University scientist.

The method, regarded as a major advance in the field of protein chemistry, now makes it possible for scientists to study the transformation of inactive protein molecules into active ones.

A better understanding of this process is believed to bring scientists a step closer toward the much discussed goal of making deliberate alterations in the protein structure of human cells to treat genetic diseases and cancer.

The scientist is Dr. Oleg Jardetzky, professor of pharmacology at the Stanford University School of Medicine. He described his work Wednesday at the meeting of the American Society of Biological Chemists in San Francisco.

Proteins are chemically complex substances made up of a number of so-called amino acids. The nature of a specific protein depends on the kinds and amount of amino acids and the number in which they are combined.

"The genetic code (DNA) specifies the exact sequence in which the amino acids are to be connected to form a particular protein. But this extended chain of amino acids must be folded into an exact structure before the protein can act," Dr. Jardetzky said.

However, the folding process has so far eluded scientists because methods for studying it in detail have been lacking.

Dr. Jardetzky's method uses a modified version of a spectroscopic technique developed at Stanford 25 years ago by Nobel Laureate Felix Bloch, professor of physics. The technique is known as nuclear magnetic resonance.

By labeling amino acids with isotopes, a scientist can look at selected amino acids in the protein and chart the course of the structural change during folding.

-more-

Dr. Oleg Jardetzky/protein folding process

222

Dr. Jardetzky has already demonstrated the effectiveness of the method by studying the folding process in the protein of staphylococcus, the bacterium which causes "staph" infections.

He described these steps in the folding process:

The "staph" protein is first made as a simple string of amino acids. Almost the whole chain has to be completed before the folding can begin.

Folding takes place in several steps, at least seven of which can be seen spectroscopically.

The first to form are tight coils known as alpha-helices discovered by Nobel Laureate Linus Pauling 20 years ago. It is followed by formation of a loop known as a pleated sheet. Next to form are irregularly shaped clumps held together by looser bonds, and the last step is the attachment of the loose ends of the string to the folded structure. The active site is complete on the next to the last step.

Dr. Jardetzky predicted that when the detailed mechanism of folding is understood "one would be in a position to design and synthesize novel proteins with specific and potentially useful functions not normally found in nature."

Abnormal protein folding has been associated with genetic diseases and cancer.

City Desks and Science Writers: An internation symposium on psoriasis, the first of its kind, will be held at Stanford University July 7 through 10, 1971.

Psoriasis experts from all over the world will get together for a comprehensive discussion of the disease, which affects at least 1 out of 50 persons in the United States.

The exact cause of this common skin disorder which causes itching and scaling is not known. Basic and clinical research in recent years have led to better understanding of the disease and its control, although no specific cure has been found.

Childhood psoriasis, epidemiology and psychological factors will be among the more general topics discussed. However, emphasis will be on numerous clinical lectures and an examination of the biological approaches to the study of the disease. Specific topics include DNA synthesis in psoriasis, lipid metabolism, immunologic factors, screening techniques and scanning electron microscopy in psoriasis.

In addition, experimental and current therapy and complications will also be reviewed. Topics on the agenda include discussion of topically active chemotherapeutic agents, the chemistry and pharmacology in the use of tars and anthrain as well as topical and systemic treatments with steroids, and the use of methotrexate.

Among the speakers at the symposium will be Dr. Eugene Farber, professor and chairman of the department of dermatology at Stanford; Dr. Gunnar Lomholt from Mulago Hospital in Uganda, East Africa; Dr. Autoro Mom of Hospital Argerich in Buenos Aires; Dr. Toshiaki Yasuda, chairman of the department of dermatology at the Toho School of Medicine in Tokyo; Dr. Otto Braun-Falco, director of dermatology at Universitats-Klinik in Munich; and Dr. John Kenney, Jr. from Howard University in Washington, D.C. These men, as well as other lecturers at the conference, are renowned for the work they have done in the study of psoriasis. There will be more than 40 speakers from all over the world, from countries representing South America, Europe, the Far East and Africa. About 300 dermatology specialists are expected to attend.

The symposium is a report of the psoriasis task force of the National Program for Dermatology, a group sponsored by the dermatologists throughout the country. It was set up three years ago with the aim of conquering disability due to skin diseases.

The conference is under the auspices of the department of dermatology at Stanford. It is underwritten in part by a grant to the department from the Schering Corporation.

Science and medical writers are invited. The conference will be on the Stanford campus. If you plan to cover the meeting, please notify the Stanford Medical Center News Bureau by returning the form below:

STANFORD -- Dr. John L. Wilson, acting dean and executive officer of the Stanford University Medical Center, received the Henry J. Kaiser Award for excellence in teaching at the annual convocation of the Stanford University School of Medicine, Sunday evening June 13.

The School presented awards to 10 medical students, including 7 graduating students. Diplomas were presented to 64 men and 5 women medical graduates.

Fifteen students, 8 women and 7 men, received master's degrees; and 28 received Ph.D.'s, including 19 men and 9 women. In addition, the School of Nursing presented diplomas to 14 graduates, and the School of Medicine awarded a Bachelor of Arts degree to one student in medical microbiology.

At the convocation, James G. Bowerman received the Robert H. Alway Book Award. Named in honor of Dr. Alway, dean of the Medical School from 1958-64, the award is given annually to a student "who has availed himself especially well of the unique opportunities afforded by the Stanford Plan" (five-year plan).

James M. Ferguson was presented the Borden Undergraduate Research Award, given by the Borden Company Foundation, Inc., to the graduate "who has completed the most meritorious research during his medical training."

The Harold K. Faber Pediatric Award was presented to Robert C. Hackman in recognition of his "outstanding accomplishments as a student of pediatrics and of his potential as a contributor to child health."

The first Robert J. Glaser Book Award was given to William R. Korns. The award is presented in recognition of Dr. Glaser's contributions as dean of the School of Medicine (1965-70) to the student in the graduating class "who has displayed outstanding characteristics of leadership."

The winner of the Lowell A. Rantz Memorial Award "to the student who has distinguished himself in the field of infectious diseases" was James M. Hughes.

John W. Fitzgerald received the Upjohn Achievement Award, given by the Upjohn Company to the graduating student exhibiting "outstanding clinical performance."

Merrill Eric Gershwin received the L.A. and Marian S. Hopkins Award, presented to the outstanding graduating student in dermatology. Gershwin also received the Robert M. Shelton Alumni Award of $750.

Three medical students, not members of the graduating class, received $500 "Alumni Scholar" awards, including Year II student Joseph R. Hopkins, Year III student Carol S. Portlock, and Year IV student F. Wells Shoemaker.

-more-

The awards were presented by Miss Grace E. Ringressy, professor and director of the School of Nursing, and Dr. James B. D. Mark, associate dean for student affairs.

Michael Francis Dillon, representing the graduating class, presented the annual Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine to Dr. Richard L. Kempson, associate professor of pathology.

The faculty address was delivered by Dr. R. Hewlett Lee, clinical associate professor of surgery. Following his address, the diplomas were presented by acting dean Dr. Wilson and Miss Ringressy.

Award winners, their home towns and parents' names are listed below.

James G. Bowerman, son of Mr. and Mrs. Harold Bowerman, Box 73, Leaf River, Illinois.

James M. Ferguson, of 1160 California Avenue, Palo Alto (son of Mr. and Mrs. V. B. Ferguson, 109 St. James Drive, Piedmont, Calif.).

John W. Fitzgerald, son of Mrs. Annette Fitzgerald, 51 E. Hoover, Phoenix, Arizona.

M. Eric Gershwin, son of Mr. and Mrs. George Gershwin, 8 Maurice Lane, Suffern, N.Y.

Robert C. Hackman, of 70F Escondido Village, Stanford, Calif.

James M. Hughes, son of Mr. and Mrs. James P. Hughes, 124 Guilford Rd., Piedmont, Calif.

William R. Korns, son of Mr. and Mrs. William L. Korns, Box 1363, Provo, Utah. ###6/15/71

STANFORD -- The Stanford University School of Medicine announced today (July 14) the creation of a Lipid Research Clinic and Specialized Center of Research (SCOR) to conduct a wide-ranging investigation of treatment and prevention of heart disease.

The new programs, supported by federal grants totalling $773,387 the first year and projected at almost $4 million over the next five years, reflect a new commitment by the federal government to the prevention of heart disease.

A diverse research team, incorporating faculty members of Stanford's School of Humanities and Sciences as well as the School of Medicine, will conduct the studies.

Included in the anticipated five-year programs will be investigations of metabolic abnormalities and levels of blood lipids (fats, cholesterol and other compounds) in relation to heart disease; epidemiology (prevalence, distribution and control) of the disease in communities; effects of family structure, attitude and motivation on behavior toward health issues; and methods of modifying behavior to aid in effective prevention of the disease.

Dr. John W. Farquhar, associate professor of medicine at the Medical School and a well known researcher in heart disease, is the director of the Lipid Research Clinic and SCOR program. Dr. Peter D. Wood, research associate in medicine and prominent lipid chemist, is the deputy director of both.

The two closely-tied programs are being funded by the National Heart and Lung Institute as part of a broad new federal effort to combat heart disease. Nineteen research centers have been established across the country, including six Lipid Research Clinics and 13 SCOR centers for arteriosclerosis. Fifteen medical schools are involved, with Stanford and three other schools receiving grants for both centers.

The Stanford grants are expected to run almost concurrently for at least five years. The SCOR program (supported by a grant of $363,514 for the first year) was initiated June 1, the Lipid Research Clinic (funded by a $409,873 contract for the first year) on June 22.

"The National Institutes of Health have made it understood that this is a long-range commitment," Wood said. "Though the contracts are to be renewed annually, their estimate of the minimum time these programs will be funded is five years."

Farquhar called the establishment of the 19 research centers "a great new experiment" in one of the most pressing areas of medical study.

"We have an epidemic of coronary heart disease in this country that is largely preventable in younger age," he said. "It's a national tragedy that requires attention which is long overdue. These grants are timely entrees into this area of preventive medicine.

"Our studies will hopefully furnish us with information on who has heart disease, who has the precursors of it, and what can be done to treat existing disease and prevent its future occurrence.

-more-

"A large part of our effort will be to study the epidemiology of heart disease in communities. We've enlisted the help of a group of behavioral scientists in a team approach to learn about attitudes and motivation in behavior toward health issues, and means of changing behavior which can affect heart disease."

Following exhaustive studies of factors which influence conduct related to health, Stanford behavioral scientists will prepare mass media campaigns designed to bring about behavior change, and will also test the separate effects of frequent personal sessions (conducted in an encounter group fashion) on behavior change.

"We'll be trying to persuade people to change their behavior with respect to habits which affect coronary disease," Wood said. "These changes will probably involve moderate exercise, weight loss, cutting down or giving up smoking, and modified diets.

"In this effort we'll utilize films, radio, television and newspapers. However, we don't know that these media are effective in changing behavior, and one purpose of our studies is to first determine what are the minimum requirements for achieving important degrees of change."

The"team" aspect in these studies is emphasized to the extent that information gathered at the 19 nationwide centers will be continually compiled and compared.

Within Stanford's programs, inpatient clinic research findings will be linked to community studies, so that the choice of strategies for intervention in communities will be dictated by the results of inpatient research, Farquhar said.

Wood will supervise and coordinate the setting up of accurate semi-automatic measurement of plasma lipoproteins (components of blood which carry cholesterol and fat). Other clinical inpatient research will involve studies of metabolic abnormalities associated with heart disease.

"Another component of our studies will be the development of an ultrasound method for the early detection of arterial disease by non-invasive techniques," Farquhar said.

Both supporting agencies are divisions of the National Heart and Lung Institute, and Farquhar noted that the Stanford Lipid Research and SCOR programs are blended together, to a large extent.

Several faculty members from Stanford's School of Humanities and Sciences will be involved in these studies, including Department of Communication chairman Dr. Nathan Maccoby; Dr. Henry Breitrose, associate professor of communication; and Dr. Clifford R. Barnett, professor of anthropology. Miss Janet Voelker, of the Department of Communication will be film research supervisor.

In addition to Farquhar and Wood, researchers from the School of Medicine include Byron W. Brown, professor of biostatistics in the Department of Community and Preventive Medicine; Dr. Abraham Silvers, research associate in medicine; Dr. Gerald M. Reaven, professor of medicine; Dr. Donald C. Harrison, associate professor of medicine; Dr. Richard L. Popp, assistant professor of medicine; Dr. Jobst von der Groeben, professor of medicine in anesthesia; and Dr. Michael P. Stern, instructor in medicine.

STANFORD -- Several national authorities on childhood development will be speaking to physicians at a conference June 18 at Children's Hospital at Stanford.

The overall topic is "The Child and the Changing Environment," the seventh annual Harold K. Faber Clinical Symposium.

Dr. Paul Gyorgy, emeritus professor of pediatrics, Philadelphia General Hospital, will talk on "Nutrition and the Developing Child"; Dr. Julius Richmond, chief psychiatrist at the Children's Hospital Medical Center in Boston will speak on "The Child and Society" and Dr. David E. Smith, assistant clinical professor of toxicology at UC Medical Center, San Francisco will talk on "Drug Abuse - 1971."

Stanford speakers include Dr. Norman Kretchmer, chief of the division of developmental biology, who will give the Faber lecture on "Growth and Adaptation" and Dr. Philip Sunshine, director of nurseries and associate professor of pediatrics, whose talk is on the "Environment of the Neonate at Risk."

The meeting will start at 9:30 a.m., June 18, in the auditorium at Children's Hospital at Stanford, 520 Willow Road. It is not open to the public, but science and medical writers in the area are invited to attend.

STANFORD -- A library in international health will be established at Stanford University Medical Center. The library will be named in honor of Dr. Quentin M. Geiman, professor emeritus of the department of community and preventive medicine at Stanford. Dr. Geiman, who is a noted specialist in tropical diseases and has done extensive work with malaria, was also director of the parasitic diagnostic laboratory before he became professor emeritus in 1970.

At Stanford since 1955, he developed an elective training program in tropical health which included traveling scholarships for students. In the past decade, he has arranged for more than 60 medical students to study overseas.

Dr. Geiman has given a collection of his own books accumulated over the years as a start for the new library.

In addition, teaching and reference materials dealing with health and medical programs especially in tropical and developing countries will be purchased. Included will be government health reports put out by the ministries of such countries as well as specialized journals not available in Lane Medical Library.

A surprise announcement of the funds to establish the library was made by Dr. James P. Hughes, vice president of Kaiser Foundation International (KFI), at a reception at Stanford on May 20, commemorating Dr. Geiman's retirement. In addition to KFI, library sponsors include Standard Oil Company of California and Standard Oil of New Jersey.

The library, to be housed in the department, will be under the direction of Dr. Paul F. Basch, associate professor of international health at Stanford.

STANFORD -- Proposed legislation making California hospitals and blood banks immune to legal action from patients who develop hepatitis from blood transfusions "should be amended or categorically rejected," a Stanford University surgeon said Monday (June 7).

Dr. J. Garrott Allen, professor of surgery at the Stanford University School of Medicine, declared that the bill under consideration (AB-2889) in its present form "is not good public policy nor is it in the interest of the welfare of the patient."

Allen, a nationally known expert on blood diseases, made his views known in a letter sent to the State Assembly committee on health, which will recommend action on the legislation.

As it now stands, the bill will, in essence, continue a present law which does not give patients any protection against transfusion hepatitis, Allen said.

Hospitals and blood banks involved in transfusions will remain exempt from any legal responsibility to the patient.

"This is an evasion of their responsibilities when the law actually can be easily changed to become an effective force for upgrading our entire national blood collection program," Allen said.

Currently, commercial blood banks offer a substantially inferior product than the blood bank whose source depends entirely on volunteer donors, Allen charged. "If people were made aware of the potential hazards of commercial blood, they would be much more inclined to participate in a voluntary donor program than they have in the past. There should be enough volunteer blood for everyone."

He pointed out that transfusion hepatitis occurs 10 to 12 times more frequently from blood drawn from commercial and prison donors than when the donors are volunteers, such as friends, relatives, service clubs and church groups. He added that 90 per cent of the hepatitis cases resulting from transfusions develop from blood obtained from commercial or prison sources. The infection rate runs as high as one out of every 25 transfusions. "This continuing hazard is guaranteed by AB-2889 unless amended, to remain at this unnecessarily high rate," Allen wrote the legislators.

At least 450,000 hospital days are consumed each year by patients who develop hepatitis, he said. "However, the bill actually encourages the use of commercial blood and so raises the cost of Blue Shield and other insurance policies that pay for blood, including Medicare," Allen continued. "The patient does not feel it necessary to get volunteer replacement for his blood, because his insurance company will pay the hospital, the hospital will pay the blood bank and the blood bank will buy more blood from commercial donors. The proposed bill discourages the use of volunteer donors and the development of a reliable program." Consequently, it helps to keep the cost of blood transfusions and hospitalization high, he noted.

In addition, "it in no way guarantees that the patient who recruits volunteers of his own blood group will receive only volunteer blood and not commercial blood," Allen continued.

-more-

While there is an existing test for hepatitis, three out of four infectious donors still are not detected, he noted. "One can do much better, by simply eliminating the use of commercial and prison donors, or at least regulating their use while a volunteer program is set up. This step in itself would stimulate recruitment of volunteer donors on a sustained basis."

Allen pointed out that the State of Washington has just passed a law which does offer some protection to its citizens. The Washington law holds that hospitals are liable if a case of hepatitis arises from a transfusion from a commercial or prison donor, but not from volunteer donors.

According to Allen, the Washington law is a "start in the right direction," in that it at least encourages development of volunteer blood banks and the maintenance of good records.

"We can do much better than AB-2889," Allen wrote. "As it is presently written, it is a very dangerous bill."

He will testify against the bill and offer amendments when it is considered June 14. For many years Dr. Allen has been trying to reduce the hazard of hepatitis from transfusions. In 1958, he was the first to demonstrate that the incidence of hepatitis in commercial donors was many times higher than from volunteer groups.

Also testifying against the bill will be Dr. Marc Franklin, professor of law at Stanford. Dr. Franklin will testify on the legal aspects of the problem.

FOR IMMEDIATE RELEASE

STANFORD —

Dr. Clayton Rich, associate dean for research and clinical affairs at the University of Washington School of Medicine, was named today (July 28) as Dean of the Stanford University School of Medicine and Vice President for Medical Affairs.

The appointment, announced by Provost and Acting President William F. Miller on behalf of President Richard W. Lyman, is effective Sept. 1.

Dr. Rich, 47, also was appointed professor of medicine. He succeeds Dr. John L. Wilson, who has served as acting dean since Dr. Robert L. Glaser resigned August 31, 1970 to become Vice President of the Commonwealth Fund in New York.

His appointment culminated a year-long search by a faculty-student committee. More than 170 candidates were considered for the deanship.

"Dr. Rich brings a great deal of enthusiasm and talent to the deanship," Provost Miller said. "Both the President and I are delighted with this fine appointment."

Dr. Wilson said. "We all are anticipating his arrival and looking forward to working with him in the interests of the Medical School."

Dr. Rich, a native of New York City, was educated at the Putney School in Vermont and Swarthmore College. He received his M.D. in 1948 from Cornell University. He served his internship and residency at the Albany Hospital and Union University, and received additional clinical training at Cornell Medical College.

Before becoming an assistant professor of medicine at the University of Washington in 1960, he was engaged in research, teaching and patient care at Rockefeller University.

He was promoted to professor of medicine in 1967, and a year later became associate dean. He also served as chief of staff of the Veterans Administration Hospital in Seattle, which is closely associated with the Medical School there, and as medical director of the University Hospital.

In 1970, Dr. Rich was named associate dean for research and clinical affairs, his present position.

His research has been in endocrinology, specializing in diseases of the bone. His publications include more than 80 papers and abstracts.

Dr. Rich said that he believes medical schools will share with other medical agencies the major job of solving the nation's health care delivery problems.

"The whole area of delivery of health care is terribly important," he said. "It has become apparent in the past few years that the system in this country isn't working very well. We'll have to devise better ways of providing proper health care to everyone, not just a few.

"I see the primary role of medical schools in the health care scheme as that of innovation, and applying research methods to the problem."

Dr. Rich believes that, in coming years, there will be increased interaction between medicine and the other academic disciplines.

He and his wife, Scotty, have a son, 16, now attending Putney School. Mrs. Rich's father, the late Melvi G. Hodgkinson, attended Stanford as a member of the Class of 1925.

Dr. Rich holds memberships in the Association of American Physicians, American Society for Clinical Investigation, American College of Physicians, Western Society for Clinical Research (which he served as Vice President), Endocrine Society, Western Association of Physicians, Sigma Xi, King County and American Medical Associations, Seattle Academy of Internal Medicine, and Society for Experimental Biology and Medicine.

STANFORD -- Seven Stanford University scientists have received cancer research grants from the American Cancer Society totaling $445,619, including one of $163,463 to Dr. Henry S. Kaplan--the largest individual grant ever made by the Society in California.

Announcement of the awards was made today (July 22) jointly by the Society's state president, Dr. L. Robert Martin, and Dr. John L. Wilson, acting dean of the Stanford School of Medicine.

The Stanford total includes a $35,000 institutional grant.

Kaplan, professor and chairman of the Department of Radiology, received a one-year grant to support his research into chemical inhibitors of the repair of radiation damaged cells.

Recently, Kaplan and Drs. Kendric C. Smith and Christopher D. Town discovered a mechanism by which cancer cells repair themselves after being damaged by X rays. The doctors believe that by administering drugs to inhibit this repair process, they can make cancer cells more sensitive to radiation.

All the Stanford grants were awarded retroactively from July 1.

In addition to Kaplan, the other Stanford recipients are:

. Dr. David A. Clayton, assistant professor of pathology. He received a $94,946 grant for two years to support research on leukemia and the hereditary molecule, DNA.

. Dr. Paul Berg, professor and chairman of the Department of Biochemistry. He received a one-year award of $30,902 to study the effects of viral genes on cell growth patterns.

. Dr. Stanley N. Cohen, assistant professor of medicine and head of the Division of Clinical Pharmacology. He was awarded a one-year stipend of $30,452 to study bacterial gene control mechanisms.

Dr. Richard D. Evans. Evans received a four-year postdoctoral research scholarship of $57,435 to attend medical school and do research in radiobiology under Kaplan. A physicist from Great Britain, Evans was a research associate at the Sloan-Kettering Cancer Institute from 1968-70 and is also a former associate professor of radiology in physics at Cornell Medical College. He is seeking his medical degree so that he may "treat cancer patients directly."

. Dr. Ellen L. Taylor. She received a two-year postdoctoral fellowship of $16,705.

. Dr. Robert C. Grant. He received a two-year postdoctoral fellowship of $16,716.

STANFORD -- The Stanford University School of Medicine has received a $1 million grant from the National Cancer Institute (NCI) for continued support of the 10-year-old Clinical Radiotherapy Cancer Research Center, acting dean John L. Wilson announced today (July 19).

The program is under the direction of Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology, and Dr. Malcolm A. Bagshaw, professor and director of the Radiation Therapy Division.

The grant of $1,086,403 will be awarded retroactively for a period of one year beginning March 1, 1971.

The research center was established in August of 1961 with the support of a $943,412 grant from the NCI for the first year. Allocations have been negotiated annually since then.

In the past decade, between 200 and 500 patients per year have been treated through this program.

Major research at the center involves clinical investigations into cancers of the lymphoid tissue, particularly Hodgkins' Disease, and the study of super-voltage radiotherapy techniques, including the use of drugs and surgery in combination with radiation treatment.

STANFORD -- A new study to unravel gene control mechanisms in human cancer cells will be conducted by a Stanford University doctor under a grant from the National Cancer Institute.

The study will be directed by Dr. John H. Frenster of the Department of Medicine.

Frenster said that human cancer cells often display an embryonic pattern of proteins on the cell surface, which is similar to the embryonic patterns that can be induced in animal cancer cells by viruses, chemicals or radiation.

Control of this molecular process, which is known as gene de-repression, will be a chief focus of the study.

The molecular process, Frenster explained, which triggers the return to embryonic patterns, involves "turning on" previously repressed genes in the cell nucleus. This abnormal process plays a central role in the conversion of normal cells to cancer cells, Frenster said. "By a better understanding of how these cancer cells 'turn on,' we may be able to develop a process for returning these cells to normal behavior."

The three year program is funded for $117,769.

STANFORD -- The Stanford University School of Medicine announced today (July 14) the creation of a Lipid Research Clinic and Specialized Center of Research (SCOR) to conduct a wide-ranging investigation of treatment and prevention of heart disease.

The new programs, supported by federal grants totalling $773,387 the first year and projected at almost $4 million over the next five years, reflect a new commitment by the federal government to the prevention of heart disease.

A diverse research team, incorporating faculty members of Stanford's School of Humanities and Sciences as well as the School of Medicine, will conduct the studies.

Included in the anticipated five-year programs will be investigations of metabolic abnormalities and levels of blood lipids (fats, cholesterol and other compounds) in relation to heart disease; epidemiology (prevalence, distribution and control) of the disease in communities; effects of family structure, attitude and motivation on behavior toward health issues; and methods of modifying behavior to aid in effective prevention of the disease.

Dr. John W. Farquhar, associate professor of medicine at the Medical School and a well known researcher in heart disease, is the director of the Lipid Research Clinic and SCOR program. Dr. Peter D. Wood, research associate in medicine and prominent lipid chemist, is the deputy director of both.

The two closely-tied programs are being funded by the National Heart and Lung Institute as part of a broad new federal effort to combat heart disease. Nineteen research centers have been established across the country, including six Lipid Research Clinics and 13 SCOR centers for arteriosclerosis. Fifteen medical schools are involved, with Stanford and three other schools receiving grants for both centers.

The Stanford grants are expected to run almost concurrently for at least five years. The SCOR program (supported by a grant of $363,514 for the first year) was initiated June 1, the Lipid Research Clinic (funded by a $409,873 contract for the first year) on June 22.

"The National Institutes of Health have made it understood that this is a long-range commitment," Wood said. "Though the contracts are to be renewed annually, their estimate of the minimum time these programs will be funded is five years."

Farquhar called the establishment of the 19 research centers "a great new experiment" in one of the most pressing areas of medical study.

"We have an epidemic of coronary heart disease in this country that is largely preventable in younger age," he said. "It's a national tragedy that requires attention which is long overdue. These grants are timely entrees into this area of preventive medicine.

"Our studies will hopefully furnish us with information on who has heart disease, who has the precursors of it, and what can be done to treat existing disease and prevent its future occurrence.

-more-

"A large part of our effort will be to study the epidemiology of heart disease in communities. We've enlisted the help of a group of behavioral scientists in a team approach to learn about attitudes and motivation in behavior toward health issues, and means of changing behavior which can affect heart disease."

Following exhaustive studies of factors which influence conduct related to health, Stanford behavioral scientists will prepare mass media campaigns designed to bring about behavior change, and will also test the separate effects of frequent personal sessions (conducted in an encounter group fashion) on behavior change.

"We'll be trying to persuade people to change their behavior with respect to habits which affect coronary disease," Wood said. "These changes will probably involve moderate exercise, weight loss, cutting down or giving up smoking, and modified diets.

"In this effort we'll utilize films, radio, television and newspapers. However, we don't know that these media are effective in changing behavior, and one purpose of our studies is to first determine what are the minimum requirements for achieving important degrees of change."

The"team" aspect in these studies is emphasized to the extent that information gathered at the 19 nationwide centers will be continually compiled and compared.

Within Stanford's programs, inpatient clinic research findings will be linked to community studies, so that the choice of strategies for intervention in communities will be dictated by the results of inpatient research, Farquhar said.

Wood will supervise and coordinate the setting up of accurate semi-automatic measurement of plasma lipoproteins (components of blood which carry cholesterol and fat). Other clinical inpatient research will involve studies of metabolic abnormalities associated with heart disease.

"Another component of our studies will be the development of an ultrasound method for the early detection of arterial disease by non-invasive techniques," Farquhar said.

Both supporting agencies are divisions of the National Heart and Lung Institute, and Farquhar noted that the Stanford Lipid Research and SCOR programs are blended together, to a large extent.

Several faculty members from Stanford's School of Humanities and Sciences will be involved in these studies, including Department of Communication chairman Dr. Nathan Maccoby; Dr. Henry Breitrose, associate professor of communication; and Dr. Clifford R. Barnett, professor of anthropology. Miss Janet Voelker, of the Department of Communication will be film research supervisor.

In addition to Farquhar and Wood, researchers from the School of Medicine include Byron W. Brown, professor of biostatistics in the Department of Community and Preventive Medicine; Dr. Abraham Silvers, research associate in medicine; Dr. Gerald M. Reaven, professor of medicine; Dr. Donald C. Harrison, associate professor of medicine; Dr. Richard L. Popp, assistant professor of medicine; Dr. Jobst von der Groeben, professor of medicine in anesthesia; and Dr. Michael P. Stern, instructor in medicine.

STANFORD -- Stanford University scientists have reported a fundamental discovery believed to pave the way for improvements in X-ray techniques for cancer treatment.

Drs. Christopher D. Town, Kendric C. Smith, and Henry S. Kaplan of the Stanford radiology department, have discovered a new mechanism by which cells repair the strands of the crucial chemical DNA -- deoxyribonucleic acid. Their findings were reported in the May 21 issue of Science.

DNA is the molecule of heredity in living cells. The sequence of chemicals in the strands of DNA in a cell constitute a code that gives the cell its hereditary instructions, telling the cell what it can make and what it can become.

X rays produce breaks in the DNA chains of cells. Many of these chain breaks can be repaired by the cell. Scientists are interested in cellular repair mechanisms because administration of drugs that interfere with DNA repair processes should make cancer cells more sensitive to radiation treatment.

The discovery of the new system for the repair of DNA was facilitated by the isolation in 1969 by Drs. Paula de Lucia and John Cairns at Cold Spring Harbor Laboratory, New York, of a bacterial mutant that is deficient in the enzyme DNA polymerase. This enzyme was discovered by Stanford's Nobel Laureate Arthur Kornberg.

The bacterium that is deficient in DNA polymerase grows normally but is easily killed by X rays, the scientists said.

While investigating the cause of this sensitivity to X rays, Dr. Smith and his colleagues found the mutant was deficient in a repair system present that had not been observed before in normal bacteria because of its speed of action.

Two systems are now known to be present in bacteria (Escherichia coli) for the repair of DNA chain breaks: a rapid system mediated by DNA polymerase and a slower one controlled by the genes that control genetic recombination (previously reported by Drs. Daniel Kapp and Smith in the July 1970 Journal of Bacteriology).

-more-

DNA Repair

222

Genetic recombination refers to the process of the breakage and rejoining of chromosomes after two bacteria mate.

"Since DNA repair systems seem to be the major factor controlling cell sensitivity to radiation, the combination of radiation and drugs to selectively inhibit the repair of damage should make radiation even more effective in the treatment of cancer," Dr. Smith said.

The Stanford team has data showing that the antimalarial agent quinacrine and the antibiotic chloramphenicol facilitate the killing of bacterial cells by radiation.

"Both drugs achieved this effect by inhibiting the repair of DNA chain breaks," Dr. Smith said. He explained other drugs are also being tested.

The biochemist also revealed that preliminary studies at Stanford have shown that quinacrine also exerts its radiation-sensitizing effect on cultured mammalian cells.

The first objective in this research is to establish the principle of sensitizing cancer cells to radiation treatment by inhibiting their repair systems with drugs, Dr. Smith explained.

Once this is achieved, the Stanford scientists will turn their attention to the difficult problem of delivering sensitizing drugs to tumors while sparing normal cells in the process.

The Stanford research is being made possible by grants from the National Cancer Institute.

STANFORD -- Leading dermatologists attending an international symposium on psoriasis Saturday agreed that the controversial drug methotrexate should be a part of the care of psoriasis, but urged extreme caution in its use.

Methotrexate is a drug used primarily for treatment of leukemia. It has also been useful in treatment of severe psoriasis when other drugs and ointments have been ineffective.

Psoriasis is the disfiguring skin disease which afflicts 1 out of 50 Americans. It is incurable but can be controlled with drugs.

Recent medical reports have associated methotrexate with liver damage in patients. The drug has been the cause of malpractice suits. And the federal government is reported to be studying the drug for the purpose of restricting its use.

A study reported at the Stanford meeting by Dr. John P. Tindall of Duke University showed liver abnormalities in 66 patients treated with methotrexate over a period of three years.

"The severity of the abnormalities varied, with increasing age," Tindall said.

A second group of 58 patients, some of whom had never taken methotrexate, was studied by Tindall and his associates to determine liver abnormalities.

Interrelationships between dose of the drug and liver damage were difficult to evaluate, he said, because some patients may have had liver involvement prior to taking methotrexate.

Another speaker, Dr. Hugh Zachariae of Copenhagen, Denmark, said he biopsied livers in 47 patients, and found that 29 of them had liver abnormalities even before they were treated with methotrexate.

He said evaluation of methotrexate was difficult because there is little information about how psoriasis itself may affect the liver.

Dr. Henry H. Roenigk, Jr. of the Cleveland Clinic, said the "clinical studies clearly indicate that methotrexate is the most effective drug available to date for treating psoriasis. But it is also a dangerous drug when not used properly."

Because of the many medical and legal problems with methotrexate, many dermatologists refuse to prescribe the drug, he said.

"It would be a disservice to discontinue the careful use of methotrexate in appropriately selected patients who are willing knowingly to accept the risks," he said.

Roenigk stressed that until a better drug becomes available, doctors must recognize the hazards of methotrexate, and must know how to evaluate and prevent its serious consequences.

Zachariae agreed: "In each individual, as always in medicine, the risk of treatment should be evaluated in relation to the severity of the disease. Severe psoriatic patients are highly invalid persons."

The Saturday sessions concluded the four-day long international psoriasis symposium, co-sponsored by Stanford and the Schering Corporation.

FOR IMMEDIATE RELEASE

FOR FURTHER INFORMATION CONTACT: Gary Cavalli 415: 321-5310

STANFORD -- A psoriasis expert from East Africa has linked the low incidence of the disease in American Blacks with its relative absence in West African countries, notably Nigeria.

Dr. Gunnar Lomholt, professor of dermatology at Makerere University in Kampala, Uganda, made his remarks at a four-day international symposium on psoriasis at Stanford University.

Psoriasis is common in East Africa in contrast to West Africa (Nigeria), where it seems to be rare or very rare," Lomholt said. "This is reflected in the low incidence among the American Negroes, who mainly originate from West Africa."

Lomholt said that the tropical climate of Uganda and other East African countries "does not seem to be especially favorable for patients suffering from psoriasis." In Nigeria and Angola, where it is more humid, the disease is uncommon.

"Climate is involved," Lumholt said, "but the genetic factors are most important. The people of West and East Africa are genetically distinct. The West African belongs to the Sudan or pure Negro race, while the East African is of the Bantu or Nilo-Hamite race."

Lomholt said in his own studies of dermatology in 3,371 Black patients at Mulago Hospital in Kampala, Uganda, he found 93 cases of psoriasis, an incidence of 2.8%. He contrasted this with recent research in Nigeria and Angola, which uncovered an incidence of less than 0.5 of 1%.

Studies of psoriasis among U.S. Blacks, reported at the symposium by Dr. John A. Kenney of Howard University, indicated that psoriasis is markedly less common in American Blacks than in Whites.

STANFORD--A new formula for an old remedy was hailed Friday (July 9) as a significant advance in the treatment of psoriasis by an international panel of dermatologists meeting at Stanford University.

The substance is a combination of the 55-year-old anthralin paste with additives which reduce skin irritation and other side effects formerly associated with the old remedy.

A smooth-spreading medication, developed at Stanford University School of Medicine by Drs. Eugene M. Farber and David R. Harris, it is applied at night for 8 to 12 hours under a doctor's direction.

Harris said the best results were seen among patients hospitalized for a short period during the initial treatment with anthralin, and continuing therapy at home.

The paste is removed in the morning by brushing and the use of mineral-oil-soaked washcloth. A corticosteroid cream to soothe the skin is optional in addition to use of tar, followed by exposure to sunlight.

Once the skin clears, the paste is applied three times a week. After a few weeks it is used as needed. Staining of the skin, hair, and fingernails is a minor side effect that usually disappears after a few weeks.

More than 200 patients with psoriasis have been treated with anthralin at Stanford University Hospital over the past three years, Harris reported.

Hospitalized patients responded with clearing of the skin in an average of 6 to 10 days, he said.

Treated only as outpatients, their response was more variable. Depending on how religiously they applied the remedy, significant clearing of psoriasis was seen in three weeks or more.

Follow-up studies of 50 seriously involved psoriatic patients have shown that success of anthralin treatment depends to a large extent on the patient's willingness to assume continuing responsibility for control of his disease, Harris said.

"We have found subsequently, that many patients won't accept this responsibility," Harris said. "But for those who do, anthralin paste is the most effective topical preparation available."

Anthralin has also proved effective in psoriasis of the scalp, palms and soles, alternating with use of cortisone, he said. In the case of scalp, the pomade is left on overnight and removed in the morning by shampoo. Scalp lesions vanished within five to six weeks.

Harris's report was presented at an international symposium on psoriasis co-sponsored by the Stanford Medical School and the Schering Corporation.

Psoriasis is a common skin disorder which causes itching and scaling and affects 1 out of 50 persons in the United States.

STANFORD -- An international expert in psoriasis today said that the disease is "virtually non-existent" among the pure Indians in some Latin American countries, and pointed to this as evidence that the disease is determined by environmental as well as genetic factors.

Dr. Francisco Kerdel-Vegas, noted professor of dermatology at the Central University of Venezuela, made his comments at the International Symposium on Psoriasis at Stanford University.

"Psoriasis is almost completely absent in these groups of Indians who still live in isolated communities, where there are little opportunities for outbreeding, and where with all probability they have remained separated and living in unaltered conditions since the white man moved into the new continent," he said.

"In general, it is widely accepted that psoriasis is a disease determined by genetic factors," Kerdel-Vegas noted. But "it is obvious that to show that so many other non-genetic factors do not play an important, and perhaps a determinant role, in the precise problem of the occurrence of this disease, is difficult to prove...."

He cited a recent study by Dr. Jacinto Convit, which showed the absence of psoriasis in a total of 25,000 Indians of both sexes in 95 small villages in the Andean countries of Bolivia, Ecuador, Peru and Venezuela. These published findings, he added, have been "remarkably consistent" with many other unpublished studies by scientists researching the Indian population of Venezuela.

These communities of Amerindians "have remained isolated and untouched by the influence of the white man and 'civilization,' both from the genetic point of view and from any changes in the environment," Kerdel-Vegas said.

"In such cases," he stressed, "it is difficult...to ascribe the absence of the disease exclusively to the genetic factor.

"The way of life of this primitive people, their diet, their exposure to sunlight, and thus their pigmentation of skin, their habits, their social life, amount of physical exercise, freedom from emotional tension and hygienic factors, in summary, everything is different to the life of the civilized white man...," he said.

These findings, Kerdel-Vegas concluded indicate that environmental factors are highly significant in the epidemiology of psoriasis, and must be considered along with genetic factors in determining causes and treatment of the disease.

Another story reported by Dr. John A. Kenney of Howard University showed that psoriasis is not as common among American Blacks as it is in Whites.

Kenney said in his own study of dermatoses seen in 3,860 Negro patients, he found only 27 cases of psoriasis, an incidence of less than 0.7 of 1%. This was in marked contrast to other surveys which studied white patient groups and found an incidence of psoriasis of 4.6%.

As to the reason for a possible lower incidence of psoriasis in American Blacks, one can only speculate, Kenney said. "Certainly the suggestion that there is an inherited predisposition must be accepted," he said. "The corollary to this, that the incidence varies among different racial groups, must also be accepted."

STANFORD -- A Stanford University expert on psoriasis said Wednesday that after years of research, the disfiguring skin disease that affects some six million Americans remains incurable.

"As it stands," said Dr. Eugene Farber, "our armamentarium for the treatment of psoriasis is almost as bare as Mother Hubbard's cupboard."

Farber is professor and chairman of the Department of Dermatology. He made his comments at the opening of an International Symposium on Psoriasis at Stanford University, co-sponsored by the Schering Corporation.

"Patients consult us because they are anxious and sick and want our help," Farber told the conference. "We respond to this privileged position by prescribing therapy not much better than that of our grandfathers who were also well acquainted with ammoniated mercury, tar and anthralin.

"Although we have improved on the techniques for their use and have added corticosteroids and methotrexate, the state of the treatment of psoriasis today leaves much to be desired."

Farber said there is now an active search for development of new drugs, but not one as yet can be regarded as a winner.

Ironically, he added, there is little comfort in the information that other diseases are in need of better drugs also. He referred to the rheumatic diseases for which aspirin is still prescribed as the best treatment.

Farber called on the participants to accept the challenge and plan a decade of increased effort to solve the problem of psoriasis.

"We are very much aware that research support is infinitesimal when compared to the support of other crippling diseases," he said. "Funds allocated for research in dermatology are also small compared to expenditures by the public for creams and other skin preparations used for aesthetic reasons."

Farber said expenditures by the American public for nonmedicinal skin preparations approach $2 billion annually.

He said there are some unique features of psoriasis not present in other diseases.

- Psoriasis first of all is limited to the skin.
- There are genetic components. It is a disease built into the individual and is part of his makeup, rather than a superimposed disease.
- Although there are spontaneous remissions, psoriasis must be regarded as incurable.

"The lesions cause a stigmatizing blight, causing emotional problems and literally ruining the lives of those with severe manifestations," Farber said.

Farber said even if a successful treatment for psoriasis were found, there would not be enough dermatologists to cope with the demand of patient visits. There would be 2,000,000 severely disabled psoriatic patients requiring 50 office visits a year. The sudden demand to provide 50,000,000 additional office visits a year could not be satisfied, for this would constitute an additional 18,000 visits a year for the 3,000 board-certified dermatologists in America, he said. ### Mailed 7/7/71.

NOTE TO CITY EDITORS AND SCIENCE WRITERS

An international symposium on psoriasis, the first of its kind, will be held at Stanford University July 7 through 10 in Physics Hall 100, (Physics Tank).

Experts from all over the world will meet to discuss this common skin disorder which causes itching and scaling and affects 1 out of 50 persons in the United States.

Childhood psoriasis, epidemiology and psychological factors will be among the more general topics discussed. In addition, experimental and current therapy and complications will also be reviewed.

Topics on the agenda include drug therapy, the chemistry and pharmacology in the use of tars and anthrain as well as topical treatments with steroid drugs.

The symposium is a report of the psoriasis task force of the National Program for Dermatology, a group set up three years ago with the aim of conquering disability due to skin diseases.

The conference is sponsored by the department of dermatology of the Stanford University School of Medicine, and is supported in part by a grant from the Schering Corporation.

Science and medical writers are invited. A press room has been set up near the Physics Hall in Room Ph-103. Enclosed is a copy of the program, and map.

FOR IMMEDIATE RELEASE

STANFORD -- The Stanford University School of Medicine has announced that 21 per cent of its 77-member entering class this fall will be women--nearly double the number of women admitted in previous years.

The change is a result of a new program adopted recently by the faculty senate of the Medical School.

It calls for efforts toward a substantial increase in the proportion of women on the faculty, on the house staff (interns and residents), and the student body.

The new program was developed by the Medical School's joint committee on the status and tenure of women, and is described in a guest editorial in the July 1 issue of the prestigious New England Journal of Medicine. The editorial is authored by Dr. John P. Bunker and Dr. Judith Pool, respectively chairman and member of the joint committee.

Elsewhere in the journal there is a paid advertisement inviting women to apply for faculty openings at Stanford medical school in departments ranging from anesthesia to surgery.

Dr. Pool explained the ad is "a first step toward open recruitment" for faculty openings hitherto conducted privately or by word of mouth.

"Traditionally women have been excluded from the kind of grapevine that informs them about faculty openings," Dr. Pool said.

Describing Stanford's program in the editorial, Dr. Bunker wrote: "The action expresses Stanford's clear conviction that more women are needed in medicine nationally.

"The case for more women in medicine can be made on the basis of what medicine has to offer to women in search of a career, but equally compellingly, on the basis of what women have to offer to medicine."

Dr. Bunker said college women are eagerly seeking new professional opportunities, and this quest will become increasingly earnest as restrictions on family size become accepted.

"Actively discouraged in the past, applications by women accounted for no more than 10 per cent of the total," Dr. Bunker said. "The potential pool of professional women is large and almost untapped."

But with encouragement, he added, it should be possible to increase the number of women applicants to nearly equal that of men.

Dr. Bunker said one of the major obstacles to the recruitment of women has been the inflexibility of the curriculum in medical schools as well as in internship and residency training.

Although some medical schools have in recent years introduced flexible programs for academic reasons, they provide also an opportunity to accommodate the special needs of women students.

-more-

He said Stanford's curriculum has recently been made entirely elective, with no fixed timetable for completion of the M.D. degree. And there are courses not required to be taken by all students.

"Students may also arrange to take leave without academic penalty," Dr. Bunker said, "a feature of particular interest to women medical students with children or other house obligations."

Dr. Bunker called for similar action on the part of other medical schools to encourage women who may be interested in, but are hesitant about a medical career. Action should include improved recruitment programs, and close contacts with parents, teachers and vocational counselors who can aid in guiding young women in their choice of careers.

"We must make sure that young women know that the gates of the medical schools are open to them, and we must assure them that becoming a physician is an appropriate and realistic goal," Dr. Bunker said.

Echoing similar sentiments, Dr. Pool said Medical School departments had begun reviewing women with Ph.D. and M.D. degrees on the staff as candidates for faculty positions.

She said that of the 51 professional women in the Medical School, 8 are faculty and only 2 of them have tenured appointments. The remaining women are research associates, instructors, and senior scientists. There are nearly 300 full-time members on the Stanford medical faculty.

In spite of the small representation of women on the faculty, Dr. Pool thinks Stanford is ahead of other medical schools in opening up opportunities for women. The School was first to establish an office of women's affairs three years ago under a grant from the Macy Foundation of New York, she said.

Under Macy auspices, Medical School departments have established a program of flexible internships and residencies for women which Dr. Pool termed most successful.

"We still have a long way to go," Dr. Pool said, "but first we want young women to know that this is the new look--and that all this negativism about medicine careers for women is out of date."

Dr. Pool also said that professional women at the Medical School were working to establish a Day Care Center.

STANFORD--Hospitals can smother almost any child's development by the syndrome of institutionalism, says a pediatrician who was formerly assistant medical director at Children's Hospital at Stanford.

Dr. Helen H. Glaser, who is now in psychiatric residency training, notes that for whatever reasons children are in a hospital, they are still babies, toddlers, school-age children or teen agers with all the needs, fears and desires of these diverse aged people. Their normal needs are only complicated by the simultaneous illness.

However, hospital planners take few, if any of these needs into consideration, Dr. Glaser commented in an interview. "Yet, it is not so much a matter of money as the lack of thoughtful planning in the beginning." She added, "I have frequently seen errors of omission in the design of hospitals, simply because no one ever thought about them beforehand."

Dr. Glaser has spent the last two years studying hospital design with Roslyn Lindheim, professor of architecture at the University of California at Berkeley, and assistant dean in the school of environmental design; and Christie Coffin, research associate in architecture at UC Berkeley. The result of this study will appear in a book Environments for Sick Children to be published next spring by Harvard University Press.

Dr. Glaser hopes the study will help to generate planning of hospital environments sympathetic to different aged children.

Expert medical care must be supplemented by also meeting a child's social, emotional and developmental needs, Dr. Glaser believes. She contends that with planning, these needs can be accommodated for both acutely and chronically ill children within the hospital walls.

If medical facilities are to be used appropriately, she says, they must be comfortable, easily accessible, appropriate to the needs of children of different ages and staffed with personnel from all subgroups of the community involved.

In the forthcoming book she also proposes alternatives to hospital care, such as a medical service link to public schools.

She points out that perhaps the single most important factor affecting the needs of children in a hospital is the attitude of parents and staff toward each other.

"Today, there is a long standing atmosphere of mistrust, especially from those from a low socio-economic background," she says. "Hospitals should appear accessible and reassuring.

"Modern institutions have grown in scale to such a size that their physical expression is more monumental than human. Largeness has also resulted in an attitude of irresponsibility on the part of the users. The building tells the user that he needs not become involved."

-more-

She suggests that flexible planning can result in increased staff efficiency and less fear and boredom on the part of the children. In addition, parents gladly will give both help and cooperation to the staff and children if a space can be made for them where they "do not infringe on the nurses' domain, but are made to feel they belong," Dr. Glaser says.

Among her suggestions for parents:

. sufficient number of private rooms and baths on each nursing unit to accommodate the parents of young children.

. an area where they can prepare special foods for their children. "Most parents would be happy to do this, and would have a sense of really helping, which indeed they would be doing. They can also feed the sick child who is very apt to be finicky about his food, and help to clean up afterward."

. a comfortable, non-institutional lounge where they can relax, and get away from the hospital atmosphere for brief periods.

For the staff, Dr. Glaser suggests:

. an informal setting for team meetings, conducive to the exchange of ideas between all personnel, regardless of status position. "Physical facilities cannot bridge the social gulfs created and maintained by rigid organizational structure of the hospital," Dr. Glaser says, "but what can be done is to provide opportunities for easy informal and formal interaction and then work for its realization."

. work for the nursery and toddler staff should be organized and set up so that nurses can be assigned to particular children to care for them in all ways. "The child feels that he has a secure relationship with one real person and the nurse's own attention is not pulled in so many different directions."

. long corridors should be abolished both for the sake of the staff and the children. "Children find the long halls between X-rays, treatment, and their own rooms frightening and of course the halls waste the time and energy of the staff."

She believes the nursery rooms should be bright, with opportunities for babies to look at or have small distractions--pulleys for mobiles, patterns, rocking chairs. "Hospital architects have assumed infants do not require visual, auditory or tactile stimulus, but studies have shown that this is not true."

Toddlers' rooms should have as many links with home as possible. Items might include connection equipment for a telephone, a place to hang up photos or to see home movies, windows where they can look out onto a hospital entrance to watch for parents and to observe routine comings and goings. "In this way, the child does not feel so isolated and cut off from day to day activities."

She also suggests that:

. toilets should be low, visible and easily accessible.

. bathing and water play could be provided in a specially designed room "more like a spa rather than the aseptic hospital bathroom."

. space and opportunity should be made for the interaction of school agers and toddlers, when it is desired. "Grade school children often get enjoyment and satisfaction out of caring for younger children and they also function as protectors or playmates."

-more-

333--Dr. Helen Glaser

School children the same age and sex should be grouped together, she states. "This can be done easily only when there has been flexible planning in the beginning, such as removable partitions, and the opening up of other units as needed to compensate for the fluctuation of different children in the hospital at various times. There is no need for a not-so-sick ten-year old to be with a very sick six-year-old, though I have seen instances of this," says Dr. Glaser.

Other planning needed for schoolagers include a place of their own to display pictures and get-well cards "which seem to mean so much to them," and an area where a project can be left to work on again--not to take apart of put away to make room for treatment or eating. Closed circuit TV equipment for their own classroom participation would also be helpful.

"A nearby kitchenette is a necessity--a snack can be the event of the day," Dr. Glaser adds.

Turning to adolescents, she remarks "when they are in a hospital, they are often sicker than younger children and have more medical complications. And being confined in a hospital is particularly difficult for them. Therefore, it becomes even more crucial for the whole patient to be treated."

A suitable environment for young children in no way meets teenage needs, Dr. Glaser continues.

Among the most pressing needs for them she says are:

. a variety of special facilities, such as a place away from the bed for dining, a quiet room where they can hold a private conversation and a common room, where there could be record playing.

Also, the need for an adolescent patient to have privacy when he needs it is crucial, she believes. "Hospital curtains in no way suffice; there are many other imaginative and creative solutions that do not cost much extra money, but pay off from thoughtful planning."

Dr. Glaser is the wife of Dr. Robert J. Glaser, vice president of the Commonwealth Fund and former dean of the Stanford University School of Medicine. The Glasers are leaving the area to reside in New York City.

STANFORD -- Your memories are holograms in your head.

Optical holography produces remarkable three-dimensional images by means of laser beams.

The idea that the brain's imaging process is based on holographic memory belongs to Dr. Karl Pribram of Stanford University. For two and a half decades, the noted neurophysiologist has been exploring the mysteries of the brain--how it records, stores and retrieves information.

The trim, soft-spoken scientist says that both his own studies with cats and monkeys, and the work of other researchers have shown striking similarities between memory and holograms.

The similarity is based on the fact that holograms provide a complete three-dimensional image of the original scene. Several holograms can be superimposed on a single film plate, and the images extracted independently when some of the conditions under which they were produced are repeated. The holographic film can be cut into fragments and each fragment when illuminated will reproduce the entire image.

"These are properties shown by the brain's memory mechanisms that have puzzled scientists for years," Pribram said.

His vision of how the brain works is described in the September issue of Psychology Today, and in his new book Languages of the Brain (Prentice-Hall) published today.

Reported are experiments which show that though a portion of a laboratory animal's brain is removed, its behavior can remain substantially unaltered.

Physicists can perform a similar trick with holograms, snipping off a small corner and using it to reproject the entire three-dimensional picture.

"Tear an ordinary photograph of your family in half, and half the family disappears," says Pribram. "Do this to a hologram and recognition remains unimpaired."

"These experiments bear out a common clinical observation," says Pribram. "A man who has a stroke that destroys half or more of his visual system does not thereafter fail to recognize his family. The organization of the brain's memory store is such that particular memories are hard to wipe out."

Pribram states that the hologram, like the human brain, has a fantastic capability to retrieve and store information. Many different kinds of information can be superimposed in one hologram. Some 10 billion bits of information have been stored holographically in one cubic centimeter.

-more-

"Distributed information and the incredibly large storage capacity--two properties of the brain mechanism in recognition--are thus accounted for by the model," he says.

Pribram suggests on the basis of experimental evidence that the same set of equations and computations describes physical holography and image construction by the brain.

The physical hologram resembles a filter made when an optical image is projected onto a film placed "out-of-focus"--for example, at the focal rather than the image plane of a camera. Such out-of-focus filters can serve as sources for imaging when appropriately re-illuminated. They serve, therefore, as "memories" with the peculiar property that the information stored cannot be immediately recognized as such because it is distributed (defocussed) over the entire extent of the filter.

Evidence in support of Pribram's theory has come from experiments at Cambridge and Harvard universities. It indicates by means of electrophysiological experiments that the brain transforms information by a process which is mathematically identical to that used to make holograms.

"The experiments," he says, "account for the fact that a child who has learned to identify the letters of the alphabet by sight can recognize them no matter what size they are. The child readily identifies a 20-foot letter A on a billboard even if all the A's he has seen before then have been a quarter of an inch in height." But recognizing letters upside down is considerably more difficult, as would be predicted by the theory.

In recent years, other scientists searching for material explanation of memory have concurred in finding increased amounts of ribonucleic acid (RNA) in the brain of rats following learning activity. (RNA is the chemical that transcribes the inherited potential in deoxyribonucleic acid [DNA].)

Pribram accepts these findings, but feels RNA plays only a subsidiary role in memory function--for instance, he suggests RNA increases may merely reflect the synthesis of protein needed to establish new nerve cell connections.

"When the holographic model is taken seriously," Pribram concludes, "many paradoxes regarding brain function in perception become understandable. The outlines of the neural holographic processes are only now coming into focus, where not so long ago, only vague hobbits inhabited the land of neuromythology."

STANFORD -- Ernest Hemingway, whose novels both mirror and helped shape the 20th century American character, was a deeply troubled man, suffering from anxiety and depression which stemmed from his failure to live up to the idealized image of himself.

This is the verdict of the first psychiatric study of Hemingway who struggled with his psychic conflicts all his life, and finally committed suicide July, 1961.

The study, published in the current issue of the Archives of General Psychiatry, was done by Dr. Irvin D. Yalom, a Stanford University psychiatrist, and his wife, Dr. Marilyn Yalom, a professor of literature at the California State College at Hayward. It is based on recorded events of Hemingway's life and his writings.

Ironically, Hemingway despised psychiatrists and considered going to one as the ultimate indignity. But he attempted to work out his conflicts through the typewriter and relived them, capping each episode in his novels with an ending more satisfying to his pride than the real story, Yalom says.

"His Corona typewriter was his analyst and one can hardly disagree with him," Major General Charles T. (Buch) Lanham, one of Hemingway's closest friends, is quoted in the study. Lanham assisted the Yaloms in their research.

Two factors were important in Hemingway's failure to live up to the image he had built up for himself.

"The image was so extreme that superhuman forces would have been required to satisfy it. Secondly, a number of counterforces limited his available degree of adaptability," Yalom says.

These secondary counterforces--dependency, cravings and oedipal conflicts--were sources of anxiety in their own right and hampered the actualization of the idealized self, according to Yalom.

Yalom observes that in the retrospect of scarcely 10 years, "it appears to us that Hemingway's legacy is one more of form than of substance, that he will be remembered as a stylistic genius, but as a very narrow guide to life.

"While we appreciate the existential considerations generated by the Hemingway encounters with danger and death, we do not find the same measure of universality and timelessness we associate with a Tolstoy or a Conrad or a Camus."

Yalom suspects that Hemingway's restricted view of the world is related to his personal psychological restrictions. There are many questions he never raised about the universe. There are even more he never raised about himself.

Observe Hemingway at any point during his mature years and one meets a powerful, imposing figure--the fellow obsessed with playing the part of Ernest Hemingway, says Yalom.

-more-

"Whatever else we can see," Yalom comments, "always there is virility, strength, courage. He is the soldier searching out the eye of the battle storm. The intrepid hunter and fisherman compelled to pursue the greatest fish and stalk the most dangerous animal from the Gulf Stream to Central Africa. The athlete, swimmer, brawler, boxer, the hard drinker and hard lover who boasted he had bedded every girl he wanted and some that he had not wanted. The lover of danger, of the bullfight, of flying, of the wartime front lines. The friend of brave men, heroes, fighters, hunters, and matadors."

Yalom continues: "The image is so powerful that it obliges even the most naive observer of human nature to wonder whether a man firmly convinced of his identity would channel such a considerable proportion of his life energy into a search for masculine fulfillment."

It is well known that privately and publicly Hemingway invested inordinate energy into fulfilling his idealized image. The investment was not primarily deliberate. "He acted often not through free choice but because he was driven by some dimly understood internal pressure," Yalom writes. "He fished, hunted, and sought danger not only because he wanted to but because he had to, in order to escape some greater internal danger."

In The Snows of Kilimanjaro Hemingway suggested that he needed to kill to stay alive, the psychiatrist observes. After World War II, Hemingway complained of the emptiness of his life without the war.

Everyone has an idealized image of himself, somehow, Yalom comments, but Hemingway's idealized image was more, much more.

The development at an early age of an idealized image and the channeling of energies away from fulfillment of one's actual potential has extremely far-reaching ramifications on the developing personality, according to psychiatric theory.

Yalom elaborates: "The individual experiences great isolation as chasms arise between himself and others. He places increasingly severe demands upon himself....

"He develops a complete pride system that defines which feelings and attitudes he can permit and which he must squelch in himself.

"When the idealized image is severe and unattainable, as it was for Hemingway, tragic consequences may result: the individual cannot in real life approximate the idealized image...and he is flooded with self-hatred, which is expressed through a myriad of self-destructive mechanisms."

Hemingway, according to the study, was exceedingly dependent on praise and highly sensitive to criticism. He bore his critics' vengeance and, in a paranoid way, considered anything but unqualified praise as a conspiracy again him.

His relationship to General Lanham, quoted in Yalom's study, projects a childlike admiration for the professional soldier, with whom Hemingway compares himself unfavorably and attempts to identify.

He wrote to Lanham that others were "always jealous" of people like them, and that The Old Man and the Sea had in it everything in which they both believed. Hemingway wrote also in a period of depression that he was just killing time wishing he were a soldier like Lanham instead of a "chickenshit writer."

But it was in his novels, which Hemingway himself had labelled biographical, that his psychic conflicts swarm nakedly across the page, the psychiatric study shows.

"In his fiction, which includes some of the most moving love stories in contemporary literature, there is scarcely a single example of a successful male-female egalitarian relationship," Yalom observes. He gives these examples:

The Sun Also Rises describes the relationship of an impotent man, Jake Barnes, with the seductive, promiscuous Brett Ashley. In For Whom the Bell Tolls the worldly American Robert Jordan and the young and ingenuous Maria come together like teacher and pupil. This disparity is even more pronounced in Across the River and Into the Trees, where the 19-year-old girl Renata is called "daughter" by her lover, the 50-year-old Colonel Cantwell. In To Have and Have Not, Harry's wife Marie is an unfeminine, blowsy ex-prostitute. In The Snows of Kilimanjaro, Harry is married to a rich, intrusive woman who feeds on his vitality, and in The Short Happy Life of Francis Macomber the protagonists' wife infantilizes him until he begins to discover his authentic self, whereupon she manages to kill him by accident.

"It is as though Hemingway's attempts to portray a satisfying love-sex relationship are thwarted by a number of powerful counterforces, many of which Hemingway recognizes in his novels," writes Yalom. Looming large in such works as The Snows of Kilimanjaro, The Short Happy Life of Francis Macomber, Now I Lay Me and others, is the danger of emasculation.

"Throughout his life Hemingway considered love between man and woman as detrimental to other, truer types of relationships, such as friendship between males or man's communion with nature," Yalom comments. "One counterforce to mature love arose from a deeply based fear of women stemming from oedipal conflicts."

Hemingway also suffered from castration anxiety, says Yalom, "an idea which gains support as we consider his reaction to significant trauma."

During World War I, in which he served as an ambulance driver, Hemingway was wounded, receiving a serious and bloody injury to his legs and scrotum.

Yalom recounts the incident and believes it may have evoked terrifying, primitive fears of castration and annihilation.

"At some level of consciousness Hemingway realized this," Yalom says. "The war wound inflicted upon his fictional counterpart in his first novel, The Sun Also Rises, rendered him physically, but not psychologically impotent."

When Hemingway's typewriter was called upon to help repair the trauma he suffered in Italy, it seems to have been summoned in vain, says Yalom. He relived that injury often in his letters, conversation, and in his fiction. Each Hemingway protagonist receives a major injury, generally to an extremity.

Jake Barnes' injury, of course, was to his genitals. Lt. Henry in A Farewell to Arms suffers Hemingway's exact wound. Robert Jordan at the end of For Whom the Bell Tolls, fractures his leg and lies waiting for his death with "his heart pounding on the pine needle floor of the forest." Harry in The Snows of Kilimanjaro dies from a gangrenous injury to his knee. Harry Morgan in To Have and Have Not suffered an injury which necessitated amputation of his arm.

Of what value is this fantasied recall of injury? Does it not merely probe for pain in the same way that the tongue compulsively jars an aching tooth? Most psychiatrists will agree that the deliberate reliving of a traumatic incident represents an attempt to "desensitize" one's fear of real danger, says Yalom.

Yalom concludes: "In his posture toward self-sufficiency, physical injury and integrity, women and mature love, Hemingway fell very short of his idealized goals. His failure to do so took its toll. He was plagued by recurrent periods of self-hatred, which culminated in his suicide.

"It was the act that no Hemingway hero had ever done."

STANFORD -- A special election to create an employee advisory council will be held at Stanford University Hospital September 22 through 24.

The election, announced Monday by Dr. Thomas A. Gonda, hospital director, would give hospital employees a representative voice in decisions affecting their employment.

Specifically, according to proposed by-laws, the council's role would be: "to advise...the administration on projects and programs for the improvement of employment conditions, policies and practices of the Stanford University Hospital through joint participation of staff members."

Creation of the council represents a committment made to hospital employees by the administration last spring. The idea, however, dates back to 1968 when hospital officials had pointed to the need of formally organizing a representative body through which employees could be heard.

Forerunners of such groups are the Black Advisory Committee and the Alianza Latina, which became elective this summer. Both represent minorities at the hospital.

As set by the proposed by-laws, nominations of candidates and alternates for the 17-member advisory council are now open. Ballots will be posted September 14.

The first meeting of the new council will be October 1. Subsequently, procedures concerning election of officers and order of business will be set by the council.

All hospital employees not represented in collective bargaining agreements will be eligible to cast ballots to elect 12 delegates and alternates to the council.

In addition, CRONA (Committee for Recognition of Nursing Achievements) which represents nurses, will designate five delegates and alternates to the advisory body.

Administrators and supervisors will be ineligible to vote or to be nominated. Also excluded from voting at the special election will be some 40 licensed vocational nurses. LVN's are represented by the California Licensed Vocational Nurses Association.

The document of by-laws was developed by hospital administrative staff in informal consultation with employees. Other input came from the staff of the Department of Industrial Relations, State Conciliation Service which will supervise the election.

Dr. Gonda stressed that Black and Latin employees of the hospital would be represented on the council, in addition to having their own elected advisory committees.

He said the newly elected Black Advisory Committee and Latin Alliance would continue to focus their primary efforts on minority problems and to assist in the development of affirmative action programs designed to extend equal opportunity.

"Until affirmative action becomes a reality, with strong and effective programs, there will be a need for special input from BAC and the Alianza Latina," Dr. Gonda said.

STANFORD -- Three medical institutions in the Midpeninsula have agreed to consolidate their speech and language diagnostic and treatment programs.

Beginning September 1, all such programs will be coordinated by Stanford University's new center for communications disorders, it was announced Monday (August 23).

The agreement is a step in eliminating costly duplication, and achieving improved coordination and efficiency in the delivery of health services.

The institutions are Stanford University School of Medicine, the Palo Alto Medical Clinic, and the Children's Hospital at Stanford. Also affected are Stanford's Institute for Childhood Aphasia, and the Crippled Children's Services, which refer patients with speech-related disabilities.

Under the new plan, the Medical School's present speech clinic will be reorganized and expanded as a department of Stanford University Hospital. The center, under contract, will provide service in the other two institutions where satellite units will be maintained.

Functioning as a center for communications disorders, it will be able to treat larger numbers of patients than the present clinic, and will coordinate more effectively the existing fragmented network of speech-related rehabilitation services in the area, said Dr. Thomas A. Gonda, hospital director.

Director of the new center will be Dr. Kathryn R. Beadle, a speech and language pathologist.

Dr. Beadle said that in addition to first rate facilities, the new plan will serve as a model of "rational, coordinated diagnosis and treatment that may be followed by other institutions throughout the country."

Expansion of services will be made possible by moving certain functions from Stanford Medical Center to vacant offices in the Children's Hospital nearby.

Patient referrals and admissions, however, will be handled centrally by the Stanford facility, Dr. Beadle said.

The new center will be the only facility in the Midpeninsula offering complete services in speech, language and voice disorders for both adults and children, she said.

Dr. Beadle estimates the center will handle about 5,000 patient visits a year. She also hopes that as an independent unit, it will attract federal and private support.

"Outside financial support," she explained, "is needed because services can never be supported solely from patients' fees. To do so would mean considerable financial hardship to patients, or a sharply reduced range of service."

The added support, Dr. Beadle said, would make possible a sliding scale of fees based on financial ability so that no patient would be refused treatment because of inability to pay.

STANFORD -- A two-year study of jaundice in newborn infants will be undertaken by the Department of Pediatrics of the Stanford University School of Medicine.

The study, announced Monday, will be conducted by Dr. John D. Johnson, assistant professor of pediatrics.

His research will be supported by a $60,893 grant from the United Cerebral Palsy Research and Educational Foundation.

Jaundice in the newborn, particularly in premature babies, is known to be associated with multicrippling cerebral palsy. It is hoped that Dr. Johnson's findings may be applied to prevention or treatment of jaundice, Dr. Leon Sternfeld, director of the Foundation, said.

The disease is a common outcome of high production of bilirubin--bile--in the bloodstream. Babies with a high level of bilirubin are three times more prone to nervous system abnormalities than are those infants with low bilirubin readings.

Exchange transfusions and light therapy have been effective in some instances. However, in many cases high bilirubin rates cannot be explained.

Dr. Johnson's work will attempt to find how blood pigments are broken down in the early postnatal period, determine how much bilirubin newborns produce, and the effects of age, maturity, oxygen and drugs.

The researcher is a Stanford graduate, and was chief pediatrics resident at the Stanford Hospital in 1969, following a two-year internship and residency at Johns Hopkins Hospital, Baltimore.

Heart Transplant #34

STANFORD -- Stanford University surgeons performed their 34th heart transplant operation late Wednesday (August 18). The recipient is a 52-year-old man. He is reported in satisfactory condition.

Including the new recipient, 14 heart transplant patients operated on at Stanford are now living.

According to a new policy announced May 18 by the Hospital, the recipient's name is not announced to protect his privacy. Under the new policy, names can be released only at the patient's request. In this case, anonymity has been requested.

Donald Wanjon of Rochester, New York, who received a new heart on August 10, is now listed in very good condition.

STANFORD -- Peter Stangl, former assistant librarian at Yale University Medical Library, has been appointed new chief librarian at Lane Library at the Stanford University Medical Center. The appointment is effective September 15.

He succeeds Clara Manson, who will retire September 1, after 23 years as the top medical librarian at Stanford.

Author of a number of papers on biomedical book and journal use and retrieval in medical libraries, he has expressed interest in developing audiovisual and computer areas for Lane Library.

The Hungarian-born Stangl, 34, was graduated from Yale in 1962 with a B.A. in Russian. He then studied linguistics at the Sorbonne in Paris and at the Yale Graduate School, before obtaining his M.S. in library science at Southern Connecticut State College.

Stangl is proficient in five languages--Russian, German, French, Hungarian, and English--with some speaking proficiency in Bengali and Malay.

He began working at the Yale Medical Library in 1964, and was promoted to Assistant Librarian in 1969.

(ADVANCE FOR AM RELEASE THURSDAY, AUGUST 19, 1971)

STANFORD -- A unique approach to solving significant medical problems in heart disease will be employed by a newly-formed Stanford University-National Aeronautics and Space Administration research team.

This Biomedical Technology Transfer Team (BATeam) will apply aerospace technology generated by NASA to major problems in the field of cardiology.

The team, based at Stanford's School of Medicine, is under the direction of Dr. Donald C. Harrison, chief of the Division of Cardiology.

Under NASA contract, the project is part of NASA's Technology Utilization Program.

The Stanford group, the fourth biomedical team established throughout the country, is the first to be formed at a leading school of medicine.

The Stanford program is also unique in that it will, for the most part, concentrate on problems in only one area--cardiovascular medicine. Heart disease is the leading cause of death in the United States.

Several major medical centers on the West Coast will be contacted to obtain significant problems to work on which may be solvable by NASA technology.

The team will consist of five medical consultants and two administrative staff members from the Medical School, as well as five aerospace engineering consultants.

In addition to Harrison, the medical consultants are Drs. Edwin Alderman, William Barry, David Cannom, and Richard Crow, all from the Division of Cardiology at Stanford.

Deputy director of the program is Harry Miller, research associate and business manager of the division.

NASA currently has eight special teams charged with identifying individual problems and proposing solutions based on aerospace technology. Four of the teams concentrate on environmental problem areas. Another four, including the Stanford research team, concentrate on biomedical activities in public health research and clinical medicine.

The new program will increase the joint research efforts of Stanford and the NASA-Ames Research Center in Mountain View, California. Ames, the leading NASA center in life sciences research, will be a key technology resource for the new team.

Dr. Harrison and his staff have worked closely with Ames for the past several years, with many clinical innovations resulting. In April, a Stanford-Ames team devised a computer system to watch a movie of the beating of a patient's diseased heart--identifying dead spots or scar tissue in the heart wall, aneurysms (bubble-like projections of the heart muscle), and other disorders. ###

STANFORD--A newly-installed modular home will be the scene of "Family Focus," a unique training project in physical therapy at Stanford University Medical Center.

Supported by a five-year federal grant of over $400,000, the project will enable Stanford physical therapy students to work closely with patients and families who must make the difficult adjustments to long-term disability.

The modular home, a specially-designed prefabricated unit for family living, will serve as a "temporary home" for Hospital patients and their families for a transitional period prior to the patient's return home.

At the same time, it will be a valuable classroom for the families as well as Stanford Master's Degree candidates in physical therapy.

"The students will have the rare opportunity to work with patients and their families in a home-like setting, while the families will have an 'adjustment period' to help them adapt to or learn to cope with the family member's disability," said Helen Blood, project director and acting director of Stanford's Division of Physical Therapy.

The project will be supported by a five-year grant from the U.S. Public Health Service's Bureau of Allied Health Manpower Education, totaling $79,607 the first year and projected at $435,540 for the five year period.

It was jointly planned and will be jointly implemented by Division staff and the Mental Research Institute (MRI), a private, non-profit research institute based in Palo Alto.

The only project of its kind in the country, Family Focus is an outgrowth of Stanford's increased behavioral and social emphasis in physical therapy curriculum, Miss Blood said.

"For many years we've been working to provide training programs for students which involve them in out-of-hospital and community work as part of their education," she said. "In this case, the family and the temporary home are serving as the basis for this."

For the students, the academic and clinical aspects of their training will, for the most part, be combined.

-more-

222--Div. of Physical Therapy--Project

"Our Master's candidates will be involved in Family Focus for their full two years," said Kay Shepard, acting instructor in physical therapy and project coordinator.

"They'll assume an expanded role in working with patients, families and health professionals by taking part directly in observation, consultation, teaching patient skills, and program planning."

Apart from the academic benefits, the project is expected to have a significant impact upon the patients and families involved, said Dr. John E. Bell, Director of MRI and clinical associate professor of psychiatry at Stanford.

Bell, who teaches a course called "The Family in the Hospital," will take part in the instruction and supervision of students in the project, along with other MRI staff members. He emphasized the importance of the family in physical therapy.

"A patient who returns home with a handicap really upsets things," he said. "The family has to take over some aspects of physical therapy which the therapist performs when the patient is at the hospital. In the past, we've been acutely aware that some families don't do a very good job.

"The physical therapist can really get involved with the family and do something about this. The new program gives us this opportunity. By using the modular home, we can provide the family with a preview of how life will be when the patient returns home, and help them all cope with it."

The modular home will be set up to allow the family to engage in independent living. Adjacent but separate from the living quarters will be a combined staff office and observation room. With the family's permission, students will observe rehabilitation training and family-patient-staff conferences concerned with family readjustments.

Target date for the installation of the modular home is mid-October. It will be located behind Hoover Pavilion.

STANFORD -- The prospect of medical malpractice suits is creating a great emergency for proposed physician's assistants training programs in California, an insurance executive warned Saturday (Sept. 25).

Unless the Legislature acts to limit liability of these new health team members, future investment for training physician's assistants stands the risk of crumbling, said James F. King.

King, general manager of the malpractice division of American Mutual, addressed a symposium of 200 educators, lawyers, doctors and lawmakers at Stanford University Medical Center. The symposium, the first of its kind, was organized to discuss development of physician's assistants programs and educational standards.

The physician's assistant will be the new member of the health-care team, trained to take over some of the doctor's mounting workload. Stanford, University of California and Charles Drew Medical Center in Watts are among institutions in the state planning to train physician's assistants.

King said the new professional would be liable for his own acts, but liability would also extend to his doctor employer.

Physicians and insurance companies already face serious difficulties by a rapid escalation in malpractice suits and rising premiums, he said. King cited figures showing that in the last six months malpractice suits in the state have risen from 10 to 14 per 100 M.D.'s.

"The physician's assistant is entering an area already fraught with problems, and he will only complicate the situation," said the insurance executive.

"An onslaught of malpractice suits could destroy the new health career forever," King added.

He urged adoption of well-defined educational standards, and favorable legislation to limit liability of physician's assistants.

"Otherwise insurance premiums would go up," he predicted.

One participant disagreed. Dr. Hughes Andrus, chairman of the department of family practice at UC, Davis, said he expected physician's assistants to help reduce the number of malpractice suits, because their presence on the health team would improve the quality of care. -more-

King countered that pressure was coming from lawyers who are looking for new areas of litigation to compensate for possible loss of income since passage by several states of no-fault automobile accident legislation.

He said some 500 lawyers had recently attended a seminar in Oregon devoted exclusively to how-to-do sessions on suing doctors and hospitals.

Another speaker, Dr. Tirso del Junco, president of the California Board of Medical Examiners, said the board was developing rules to avoid difficulties.

Under the law enacted last year the board is authorized to work with medical institutions to develop such standards.

Del Junco said the first program would begin in California before the end of 1971, but he outlined concerns he felt should be resolved before they begin to affect the consumer.

These concerns are:

. The question of informed consent. At which point is the patient going to be told that some procedures will be done by a physician's assistant or that a pregnant mother will be delivered by a midwife?

. Should the new professional have some kind of identification so that he can be easily recognizable by the patient?

. Minority groups fear that physician's assistants are being created to provied health care exclusively to them, and they object to it.

. Is the physician's assistant going to provide an instrument for the doctor to make more money?

"It is the board's obligation to guard against the latter thing happening," del Junco said.

The board, he said, is aware of veteran medics coming from Vietnam with some degree of medical experience. It has been proposed that these ex-medics be utilized as physician's assistants.

"But the level of medical judgment in the battlefield is always very narrow," del Junco said, " and the board feels these medics require orientation in civilian medicine."

Del Junco said clinical experience for physician's assistants should be provided in academic medical centers.

He said in 1960, West Germany trained some 6,500 physician's assistants to cope with the doctor shortage. But when training of doctors finally caught up with the demand, physician's assistants had no place to go.

So another of the problems now being tackled by the board is mobility and future advancement of the physician's assistant in the health field, del Junco said.

STANFORD -- "Half Kidney Will Travel." The slogan belongs to Martin Monica, a 16-year-old with a kidney transplant who is constantly on the go.

Two years ago Martin was in and out of hospitals with kidney disease. He was on hemodialysis for four months and then he underwent a kidney transplant.

Now he is in a hospital again...but this time not as a patient. Martin is Stanford University Medical Center's only male candystriper. Instead of the pink and white striped uniform that gives the teenage volunteers their name, however, Martin wears the monogrammed blue shirt and trousers that are the regular attire of the male hospital volunteer.

Since August, Martin has been coming to the Medical Center every Saturday to work in patient service, where he makes rounds to talk to patients and check on their needs. It is not surprising that his favorite hospital area is the renal care unit. Normally volunteers are not allowed in the unit, but Martin has obtained special permission from the medical staff to visit patients there.

"I often talk to people on dialysis about the benefits of a kidney transplant. Many of them are afraid of the surgery and the possibility of rejection. They would prefer to remain on the artificial kidney, even though they have to come for dialysis two or three times a week," says Martin.

Artificial kidney machines sustained Martin's life for four months after his diseased kidneys were removed in 1969. Then on October 14 that year he underwent the transplant operation in which he received a healthy kidney from his mother.

It was during his convalescence from the operation that Martin embarked on the first of his many enterprises for the National Kidney Foundation's local chapter: a cooking and catering service called "Martin's Kitchen." All the money Martin makes from catering small luncheons and dinners and baking cakes and desserts to order goes to the Kidney Foundation.

The Kitchen started January, 1970 because Martin wanted something to do while he was confined to the house. He began cooking meals for his family which includes his parents, three brothers and two sisters. One day he prepared a dinner for some family friends. A guest complimenting the young chef suggested that he go into business. Five days later "Martin's Kitchen" opened.

Word of his cooking and catering talents soon spread through the Peninsula, and now Martin receives calls from San Francisco to San Jose. He has business cards which bear his slogan, and a bulletin that he issues periodically to announce something for the Kidney Foundation.

Most of his recipes were obtained from his mother and her friends, or from books, says Martin, but he has perfected his own specialties. "When I wanted to bake a pie, my mom discouraged me because making a good crust is difficult. But I went ahead and made an apple pie anyway. It came out well, and now I have perfected a pie crust that I can prepare in five minutes. In fact, I can have a lemon meringue pie ready for the oven in ten minutes," says the young chef.

-more-

Martin's favorite dessert is his special chocolate cake with sour cream. ("The sour cream keeps the cake moist," he explains.) He also bakes and decorates wedding cakes, but his biggest cake order so far was for an eight layer chocolate birthday cake.

Sweet and sour chicken with pineapple is one of Martin's most popular dishes. Another attraction is yeast rolls which he likes to bake because "it's fun to watch the dough rise."

The month of October Martin is busy with the candy sale for the Kidney Foundation. He is in charge of part of the candy supply in the MidPeninsula area. Several people will be selling boxes of candy along with Martin, and the sale will continue until all the candy is sold.

Martin's aid to the Kidney Foundation is not only financial. The dedicated teenager works continuously to make the public aware of kidney disease. "Unless it happens to you or to someone close, you probably don't know anything about it," says Martin, who admits he had never even heard of kidney disease until he became ill.

With two friends last year he made a five-minute film to illustrate the difference between dialysis machines used in the hospital and at home. He often shows this movie when he talks about kidney disease to various groups such as businessmen or veterans.

The summer of 1970 Martin and his friends campaigned fervently in favor of a state bill that would provide for more local dialysis centers in California. Existing facilities now have waiting lists of those who require dialysis, according to Martin, and many patients have to travel over 50 miles for a machine. The bill was passed.

He collects Betty Crocker coupons for artificial kidney machines for the Foundation (800,000 coupons will buy one machine.) After December, however, the coupons will no longer buy a machine so the MidPeninsula Foundation will use them toward a station wagon for transporting patients to and from dialysis centers. Martin has also bought and distributed "Support Your Kidney Foundation" bumper stickers.

"Martin's Kitchen" and the other various projects seem like full-time work, but not for an active highschooler. A member of the San Jose Bicycle Club, Martin works out daily for cycle racing and races locally every Sunday to train for the big contests in the spring. His latest hobby is photography, and he is setting up his own darkroom. To help finance his racing and photography equipment, Martin has two jobs: a paper route and a gardening service.

Since his illness, Martin has decided to become a doctor. Although he isn't sure yet what kind of physician he will be ("maybe a surgeon or pediatrician") he is certain of his medical specialty. It will be in kidney disorders.

In preparation for his future career, he plans to take several sciences courses at Cubberley High School where this year he is in the tenth grade. However, he feels that volunteering at Stanford Medical Center is a more valuable and meaningful way to prepare right now. "You must have a feeling for working in a hospital or you can't do it," says Martin. "I think you have to go through some experiences to want to do it."

STANFORD -- An all-day symposium to discuss development of programs for training physician's assistants (PA) in California will be held at Stanford University Medical Center, September 25.

The meeting will provide the first status report on PA training programs since they were sanctioned by a California law a year ago.

The law authorized the Board of Medical Examiners to work with medical institutions to develop training programs and standards for physician's assistants.

Although the law at the time was hailed as a breakthrough, putting California at the vanguard of a nationwide effort to meet the doctor shortage, no training of physician's assistants has yet started in California.

Several programs, however, are in the planning stage. According to Dr. Michael Dennis, director of Stanford's PA program, implementation of these programs has been delayed because of concern over standards.

Health professionals have expressed concern that a new class of health workers will be produced by a number of institutions without sufficient educational uniformity and established criteria for certification and mobility within the health field, Dennis said.

Dennis said he hopes the Stanford meeting will encourage airing of problems to foster careful planning by institutions undertaking PA training programs.

The meeting, which will bring together medical educators, practicing doctors, lawmakers, insurance executives and administrators is co-sponsored by the California Medical Association Commission on Health Manpower, and Area III of the California Regional Medical Programs.

The symposium will begin at 9 a.m. in Room M106, Stanford University School of Medicine.

STANFORD -- Studies in the management and understanding of psoriasis, a common skin disease that affects one out of 50 Americans, will continue at Stanford University School of Medicine under a one-year grant of $49,997 from the John A. Hartford Foundation, Inc., New York.

Announcement of the grant, effective September 1, was made jointly by Harry B. George, president of the Foundation, and Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine. The research, under the direction of Dr. Eugene M. Farber, professor and head of the Department of Dermatology, has been supported by the Foundation for several years.

While no permanent cure is yet known for the disorder, which produces reddened, scaly spots or patches on many parts of the body, various drug applications have been found to provide effective control. However, relief is usually temporary, and in most cases the psoriasis recurs.

"Clinical treatment of psoriasis is limited by our lack of knowledge of its basic nature," explains Dr. Alvin J. Cox, Jr., professor of pathology and a member of the Dermatology Department who has been working with Dr. Farber. "We believe that a defect in the mechanism which controls the growth of the epidermis (outer skin layer) leads to the psoriatic lesions, but we still do not know exactly how this mechanism functions," he says.

In order to obtain further insight into what regulates growth, the Stanford investigators are studying epidermal cells in the laboratory that have been stimulated to grow the way psoriatic cells grow. They are also observing how certain drugs applied locally act on the cell metabolism to inhibit psoriatic lesions on patients who come to Stanford University Hospital and clinics for treatment. In particular, the researchers are interested in the mode of action of the well known drug anthralin, which is one of the most effective therapeutic agents.

The Stanford team is also continuing its questionnaire studies of patients with histories of psoriasis to learn more about the specific characteristics of the illness, and how it relates to hereditary and environmental factors.

The long term work in psoriasis of Dr. Farber and his colleagues led to an international symposium on psoriasis held at Stanford in July, and co-sponsored by the Department of Dermatology. The first of its kind, the four day conference drew leading dermatologists from all over the world.

ADVANCE FOR P.M. RELEASE TUESDAY, SEPT. 14

STANFORD -- Five new rapid, inexpensive tests for the diagnosis of sickle cell anemia have been developed by a team of specialists on the disease.

Sickle cell anemia is a potentially disabling hereditary blood disease which primarily affects American Blacks.

The new findings were disclosed today at the 24th annual meeting of the American Association of Blood Banks in Chicago by the team leaders--Dr. Paul L. Wolf, associate professor of pathology and director of clinical laboratories at Stanford University Medical Center, and Dr. Robert M. Nalbandian, associate pathologist at Blodgett Memorial Hospital in Grand Rapids, Michigan.

The new tests, which may be performed within minutes for a cost of 2-8¢ per test, will permit mass screenings of the Black population across the country, Wolf said.

The red blood cells of sickle cell anemia victims become elongated, shaped like crescents or sickles. Unlike normal round, doughnut shaped red blood cells, they are inefficient oxygen carriers and have difficulty moving through the body's smaller blood vessels.

The result is seriously impeded blood flow and reduced oxygen supply to various body tissues, causing severe pain, increased infection, and often malfunction of body organs.

One Black American in 10 (approximately 2-1/2 million) carries one gene for the disorder and is said to have sickle cell trait. One in 500 (approximately 50,000) has inherited two genes and has sickle cell anemia.

A year ago the same research team unveiled a new treatment of the disease--the intravenous infusion of urea in invert sugar--based on the definition of the molecular mechanism of sickling by Dr. Makio Murayama, a biochemist at the National Institutes of Health in Bethesda, Md.

Urea, manufactured by the liver and excreted in urine, is capable of reducing the strength of the bonds formed in sickle cells and reversing the sickling process within hours.

Murayama's research into the molecular structure of hemoglobin (the oxygen-carrying protein of red blood cells which is affected by sickle cell anemia) also laid the groundwork for the team's development of the initial specific test for the diagnosis of the disease, the Murayama Test.

The Murayama Test involves placing a deoxygenated sample of the patient's blood in a 37° C. environment, and then quickly reducing the sample to 0° C. The sample will gel at 37° C and liquify at 0° if it contains hemoglobin S, the sickling hemoglobin associated with sickle cell anemia. Normal hemoglobin and other nonsickling hemoglobins will not gel at either 37° or 0°.

The first of the new tests is a simplification of the Murayama Test technique. Because of the time involved, it is the only new test not suitable for mass screenings, Wolf said.

-more-

"We've modified the test by using moist nitrogen to remove oxygen from the blood sample, instead of dry ice," he said. "This speeds up the process to about 20 minutes." Originally it took one hour.

The four remaining tests--dithionite tube test, urea-dithionite tube test, and automated adaptations of the two--utilize a solution containing dithionite to test for sickling hemoglobin.

The chemical reagents in all four dithionite tests are potassium phosphate, sodium dithionite, and saponin (snake venom).

When a blood sample containing sickling hemoglobin is introduced into the solution, the system will become turbid (clouded, muddy).

This screening procedure for sickling hemoglobin takes less than five minutes in the test tube version and 30 seconds utilizing an Autoanalyzer, both at a cost of 2¢.

If a patient tests positive in the dithionite test screenings, doctors can test specifically for sickle cell anemia by carrying the test one step further. Urea is added to the turbid system. If hemoglobin S is present, the system will uncloud.

"Only a dithionite solution containing hemoglobin S will uncloud when urea is added," Wolf said. "The urea-dithionite tube test and automated urea--dithionite test provide us with specific tests for sickle cell anemia. Non-S sickling hemoglobin will remain turbid even after urea is added."

The automated urea dithionite test requires one minute and costs from 4-8¢ per test.

Extensive field trials of the dithionite tests have been successfully undertaken at the U.S. Army Medical Research Laboratory in Fort Knox, Kentucky, Wolf said. The automated dithionite test was used to screen 7,000 troops, with hemoglobin S detected in approximately 100.

The other members of the research team are Lt. Col. Frank Camp, from the U.S. Army Medical Research Laboratory; Dr. Raymond L. Henry, associate professor of physiology at the Wayne State University School of Medicine; and Bruce M. Nichols, a chemist at Blodgett Memorial Hospital in Grand Rapids, Michigan.

STANFORD -- The first stage of a computer-based system for the prevention of undesirable drug interactions in hospitalized patients went into operation this week at Stanford University Medical Center.

The unique new system, developed by scientists in the Division of Clinical Pharmacology, utilizes Stanford's Advanced Computer for Medical Research (ACME) to automatically monitor all drugs dispensed to patients at the University Hospital.

Ultimately, it will produce a computer-generated "alert" each time a newly prescribed drug has the potential of interacting with a drug the patient is already receiving.

The program is under the direction of Dr. Stanley N. Cohen, associate professor of medicine and head of the Division of Clinical Pharmacology at the School of Medicine.

"Our objective has been to design and develop a system which can detect and identify potentially interacting drug combinations before the second drug is administered to the patient," Cohen said. "So far as we know, ours is the first comprehensive drug interaction control system of this type to be developed, and we anticipate that it may become a prototype for systems elsewhere."

In emphasizing the need for such a program, Cohen cited 1969 findings by the United States Department of Health, Education, and Welfare Task Force on Prescription Drugs, which reported that more than one-seventh of all hospital days are devoted to the care of patients who have experienced drug toxicity, at an estimated cost of $3 billion per year throughout the U.S.

"The hazards resulting from therapeutic drug use far exceed other hospitalization hazards, such as transfusion reactions and diagnostic procedures," he said.

"Recent studies have shown that more than 60 per cent of all complications experienced by hospitalized patients are caused by therapeutically administered drugs. Moreover, about one-fourth of these are due to preventable drug interactions. The system being developed here at Stanford is intended to control this important component of undesirable drug reactions."

Cohen pointed out that "the large number of potential interactions among therapeutic drugs and the pharmacologic complexities involved have made it impractical for most physicians to have adequate drug interaction information on hand when they prescribe drugs."

Consequently, Stanford's Division of Clinical Pharmacology for the past two years has been compiling a large, documented data-base of information on interacting drug combinations. This data-base, which has been entered into the ACME computer file, will be used for the drug interaction control system.

At present, the system enables Stanford's pharmacists to record drugs dispensed for patients by the of a computer-controlled television unit located in the pharmacy. After the pharmacist responds to a series of question prompts at the video terminal, the computer automatically prints out a medication label and simultaneously stores appropriate information about the drug and patient in its file.

-more-

When the completed system is put into operation, a "drug interaction report" will be generated by the computer and sent along to the physician with the medication whenever a newly prescribed drug has the potential of interacting with one a patient is already receiving.

This report will contain information about the pharmacologic basis for the interaction, potential clinical effects, clinical significance of the interaction, and documentation from medical literature.

The system will also provide safeguards against certain types of medication errors by automatically verifying patient identification numbers and bed locations, and printing out patient medication profiles for use by the Hospital nursing staff.

Additionally, it will enable the Division of Clinical Pharmacology to carry out research on mechanisms of interaction between drugs and serve as a tool for teaching medical students about the use of therapeutic drug combinations.

The system has been developed by Cohen, Drs. Marsha Armstrong and Gilbert Hunn, both postdoctoral fellows in the Division of Clinical Pharmacology, and Linda Crouse of the ACME computer facility.

ADVANCE FOR PM RELEASE WEDNESDAY, SEPTEMBER 15

STANFORD -- Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology at Stanford University Medical School is the recipient of the 1971 Robert Roesler de Villiers Award for achievement in leukemia research.

The award was presented today (September 15) to Dr. Kaplan by the Leukemia Society of America, Inc., at the banquet of the 5th International Symposium on Comparative Leukemia Research in Padua, Italy.

Established in 1954 by the Leukemia Society to recognize the contributions of leading leukemia researchers in the attack on leukemia, the de Villiers award consists of a medal and a $1,000 prize. Dr. Kaplan received the award this year "for his contributions to radiobiology, carcinogenesis and the understanding of lymphomas."

Dr. Kaplan is noted for his pioneering work in cancer and radiation. He has demonstrated an indirect mechanism in animals whereby irradiation or chemicals trigger a latent virus which induces leukemia. He has pinpointed the target cells for the virus and defined the mechanism by which bone marrow inhibits the development of leukemia unless irradiated.

At the clinical level, Dr. Kaplan adapted the linear accelerator to radiology in order to irradiate a large area. He developed a technique of irradiating all the lymph glands in the neck and thorax which has proved beneficial in treating Hodgkin's Disease and other tumors.

The Symposium, being held September 13 - 17, is principally co-sponsored by the Leukemia Society of America and the Special Virus Program of the U.S. National Cancer Institute, N.I.H. Several Italian agencies are also sponsoring the meeting.

THREE STORIES: FOR IMMEDIATE RELEASE

STANFORD -- Black employees at Stanford University Hospital are being tested for sickle cell anemia and a chemical blood deficiency which affects primarily American Blacks.

The tests are being conducted by Don Williams, a medical student, and sponsored by the Hospital and its Black Advisory Committee. Some 130 minority employees so far have been tested, and more will receive the tests next week.

Sickle cell disease is a severe hereditary disorder in which red blood cells become crescent shaped instead of round, causing a lack of oxygen in tissue cells. One Black American in 10 (approximately 2-1/2 million) carries one gene for the disorder and is said to have sickle cell trait. One in 500 (approximately 50,000) has inherited two genes and has sickle cell anemia.

Williams and his associates--all Black medical students in the project--feel that the incidence of the disease can be reduced significantly, if the carriers are identified and made aware of their problem before they have children.

The other disorder--glucose 6 phosphate dehydrogenase deficiency--is also inherited. When persons with this disorder are exposed to certain drugs, their red cells burst open causing a severe hemolytic anemia. Since a number of the drugs which cause this crisis are prescribed medicines, it is important for an individual to know whether or not he or she is affected by the disorder, Williams said.

###

STANFORD -- Dr. John P. Steward, acting director of the Fleischmann Laboratories and senior lecturer in medical microbiology, has been appointed acting associate dean for student affairs at the Stanford University School of Medicine.

Dr. Bernard W. Nelson, associate dean for student affairs, has left Stanford on a one-year leave of absence.

###

STANFORD -- Dr. Marguerite Lederberg, clinical instructor in pediatrics and community and preventive medicine, has been named coordinator of the Macy Office of Women's Affairs at the Stanford University School of Medicine.

She succeeds Dr. Barbara Arons, clinical assistant professor of psychiatry and supervising psychiatrist at Santa Clara Valley Medical Center.

The office was first opened in 1968 under a grant from the Macy Foundation of New York to study the opportunities of women in medicine at Stanford and to help establish programs to attract increasing numbers of talented women to medicine.

Over the past three years, the office has been instrumental in the development of programs of flexible internships, residencies, and fellowships for women at Stanford Medical Center. Dr. Lederberg is the wife of Stanford Nobel Laureate Joshua Lederberg, chairman of the department of genetics.

ADVANCE FOR P.M. RELEASE ON FRIDAY, SEPTEMBER 10

STANFORD -- The mass media, while successfully drawing the broad outlines of environmental problems in the United States, have continually failed to provide the specific, hard-hitting information the public needs to do something about these problems.

This is the conclusion of a 14-month study into mass media coverage of environmental problems conducted by a team of 36 Stanford students and supported by a precedent-setting National Science Foundation grant of $53,600.

The NSF grant was the first ever awarded to a project instituted and directed by graduate students.

The principal investigators--David M. Rubin, who recently obtained his Ph.D. from the Department of Communication, and David P. Sachs, a fifth-year student at the School of Medicine--disclosed their findings today at a conference on mass media and the environment at Stanford.

The day-long conference was attended by national and Bay Area reporters, editors and other media personnel responsible for environmental news.

The project resulted in three published volumes, including Rubin's discussion of media coverage in the San Francisco area and nationally (Volume II), Sachs' description of the Bay Area water system and analysis of the California Water Plan (Volume I), and an annotated bibliography of information sources on environmental subjects (Volume III).

Though he feels the media have succeeded in awakening the public consciousness to environmental problems, Rubin emphasizes that there is still much room for improvement.

"Generally, the media as a whole and the media in the Bay Area have devoted more time and space to the subject dramatically since mid-1969," Rubin says. "There is an increased awareness--they're pulling men off other beats and assigning them environmental stories.

"But they're not hiring people as environmental reporters, which would really indicate they give a damn. If you have no reporter assigned to cover environmental problems, newsroom inertia takes over and only the red hot issue will get covered."

Rubin makes seven suggestions for improved media coverage in his volume. He urges media executives not only to hire environmental reporters, but to consider establishing environmental news pages and continuing broadcast features.

Perhaps the most pressing need, as he sees it, is for the media to begin dealing with problems close to home and presenting specific findings the public can use.

"On occasion, when there is a local disaster, like the Bay oil spill, they do a good job," he says. "But if they're given a chance to name a company which has a record of violating anti-pollution standards, or to point the finger at a public official who has a poor voting record on environmental issues, they don't do it.

-more-

"In other words, if they have a chance to provide the public with specific information, they cop out."

Rubin feels advertising acceptance departments should reject misleading ads which claims a product or service will improve the quality of the environment.

"What we're really talking about are ads like Chevron F-310," he says. "We object to ads like this on two grounds: first, it's basically fraudulent. It does no more than any detergent gasoline. Second, it creates in the public consciousness the belief that industry is doing something to solve the problem. Basically, they're just after favorable publicity to take the pressure off."

Many private industries would stop polluting, Rubin belives, if the press would extend the "adversary" relationship from government to business.

"Big businesses are our biggest polluters," he says. "Until you put the glare of publicity on what business is doing, they'll be less likely to clean up."

Sachs' volume concerns the problems facing California water planners, and the possible steps that can be taken to alleviate them.

He criticizes the California State Water Project, which would divert water from the San Joaquin and Sacramento Rivers to irrigate Central Valley fields and supply Los Angeles with more water, as being both economically unsound and environmentally unwise.

"There are many reasons why we shouldn't have a city like Los Angeles growing more," Sachs says.

"Water is a limiting resource. Instead of trying to build up the water supply so that it can support a larger population, water should be used as a limiting factor to keep an area like LA from becoming even more over overpopulated than it already is."

He also argues that planners should consider using water reclamation and ground (well) water as future sources for the state's water supply, rather than building more aqueducts from the Sierras.

"You have to take into account that soft water is associated with cardiovascular disease," Sachs says. "Considerable data is being accumulated by the Japanese investigator J. Kobayashi and others to show that populations using soft water sources have higher death rates from heart disease, high blood pressure, and strokes.

"This information is particularly significant in view of the fact that mountain water transported through aqueductal systems is soft."

The project really began in 1960 at Shaker Heights High School in Cleveland, Ohio, where Rubin and Sachs first met.

Sachs' interest in environmental problems was sparked in the eighth grade, when he built a working model of a water reclamation plant while studying how to eliminate water pollution. He later won a national first prize in a Future Scientists of America contest.

His writing and research led to a 1968 article in McCall's listing 102 cities whose water supplies did not meet federal standards. According to U.S. Public Health Service officials, that article was directly responsible for initiating improvement in the water supply systems in most of those cities.

-more-

Rubin, who will teach journalism at New York University this fall, did a follow-up article for Columbia Journalism Review on how the media in those 102 cities handled the water story as revealed in McCall's.

Faculty sponsors for the Rubin-Sachs study were Nobel Laureate Dr. Joshua Lederberg, chairman of the Department of Genetics, and William L. Rivers, professor of communication.

Rubin and Rivers recently co-authored a book on the newspapers of the San Francisco Bay Area.

Included in the 36 students working on the project were a Communication team, staffed by Masters and Ph.D. candidates in Communication, and an Ecological Medicine team, comprised of graduate medical, law, geology and physics students, and undergraduate biology and human biology majors.

"The project supported four Ph.D. dissertations and six Master's Degrees in Communication," says Rubin.

STANFORD -- The number of minority applicants to the Stanford University School of Medicine has risen dramatically since the School's minority program was started in 1968, according to a faculty report made public Thursday (Sept. 2).

The report shows that for the class beginning in September this year, 299 minority students applied for admission to the Medical School compared to 17 students in 1968.

Of the 299 minority applicants, 203 were Blacks, 85 Chicanos, and 11 American Indians. More than 3,000 students applied for admission to Stanford medical school this year.

The report is based on a review of the minority program now entering its third year. It was prepared by the ad hoc committee on minority admissions and education of the Medical School's faculty senate. The committee was chaired by Dr. Grant Fletcher, associate professor of anesthesia.

Stanford will again admit 10 minority medical students this year as part of the 77-member entering class. This figure will bring the number of minority students enrolled in the medical school to 30 or about 15 per cent of all students registered in Years I through III.

Of the 30 students, 16 are Blacks, 13 Chicanos, and 1 American Indian.

The report says the increase in minority applicants has occurred, in part, spontaneously and not because of an active or systematic recruitment program.

The committee did not review the academic achievements of minority students individually, but noted that 19 of the 20 students admitted thus far under the program are in good standing.

The report also added that minority students had apparently requested little or no special tutoring that is available to all students in the Medical School.

The faculty report praised the minority admissions committee for reaching unanimity on the broad criteria for evaluation of applicants. The committee looks primarily for students with high scholastic achievement, who identify firmly with their racial-ethnic community, and are highly motivated to become doctors.

The special admissions committee includes minority representation from the faculty, student body, and local professional community. It was created because evaluation of minority candidates was felt to require the cultural background and knowledge found among members of those minority groups.

The faculty report said it would be ideal to merge the regular and special admissions committees in the future, but such a merger is impractical as long as the number of minority professors on the medical faculty is still small.

With an increased number of faculty of minority background, it should be possible in a few years to phase out the special minority admissions procedure, and return to a single admission system, the committee stated.

It also urged that an ultimate goal should be to achieve a student body including minority students in approximately their proportion to the population of Stanford's region, about 20 to 25 per cent of the total enrollment.

EDITORS: Picture and diagram of cell separator available on request if not included with article.

STANFORD: A unique new instrument to separate living cells on the basis of their fluorescence has been developed by a team of Stanford University scientists.

This sorting mechanism may open the door for new research and clinical study of treatment of diseases in man, as well as a better understanding of the body's immune system.

The Stanford cell separator utilizes photoelectric observation of fluorescence in cells in a liquid stream as the criterion for separation. Charged droplets containing the fluorescent cells are deflected electrostatically and separated from those containing non-fluorescent cells.

The instrument has been developed and clinically tested by a team that includes Dr. Leonard A. Herzenberg, professor of genetics; Dr. H. Russel Hulett, research associate in genetics; Dr. Paul L. Wolf, associate professor of pathology and director of clinical laboratories at the University Hospital; and engineers William A. Bonner and Richard G. Sweet of the genetics' instrumentation research laboratory.

Previous bulk fractionation methods--such as centrifugation, separation columns, and electrophoresis--allow sorting of large numbers of cells, but produce only limited resolution of functionally different types. The Stanford cell separator is unique in that various parameters or criteria may be used as the basis for making cells fluorescent, and thus separating them from the others in the stream.

"The net result of this," Hulett said, "is that we can take cells we want to look at or use experimentally and separate them from the rest of the cells in a general population.

"The system has proved capable of providing fractions containing large numbers of cells highly enriched in a particular functional type."

One of the most important immediate applications of the new instrument is expected to be in the study of the body's immune system.

Some body cells generate protective substances called antibodies, which are stimulated by different foreign materials or organisms (antigens). The cell separator enables scientists to separate specific antibody-producing cells from a general population, identify their chemical and biological characteristics, and determine the types of cells involved in antibody production.

If scientists can discover more about how antibodies are made, Herzenberg said, it could lead to the possible prevention of organ transplant rejection and more effective treatment of diseases such as leukemia and hemophilia.

Future possible uses may include the separation of cancer cells. Theoretically, scientists believe that if cancer cells are in the blood stream, they can be found--and treated--far earlier than has been possible in the past.

-more-

Important clinical applications of the cell sorter, Wolf noted, will involve the rapid differential counting of immature red blood cells, malaria organisms, and fetal cells in maternal blood (to research hemolytic disease of newborns), and possibly a complete white blood cell count.

The Stanford cell separation process begins when fluorescent material (fluorescein, acridine orange, or quinicrine mustard) is added to living cells in suspension in a test tube. The added molecules attach themselves to cells having particular immunochemical characteristics, and only these cells become "stained."

"In addition, we use the 'sandwich' technique of immunofluorescence," Herzenberg said. "Cells have receptors on the surface which can react with proteins and other substances. Cells with surface sites binding particular antigens are made fluorescent by reacting first with the antigen, then with a fluorescent-tagged antibody to that specific antigen."

Air pressure forces the cells in the test tube down through a glass nozzle in a fine liquid stream two-thousandths of an inch in diameter.

The liquid stream is illuminated by a laser beam. The cells pass sequentially through the beam and fluorescent light emitted by the stained cells is converted into electric signals by the use of a photomultiplier tube. A signal pulse is generated at the photomultiplier outlet whenever a fluorescent cell crosses the laser beam.

The stream is broken into a series of uniform droplets downstream of the laser, through vibration of the glass nozzle. The cell signals cause a charging voltage to be generated electronically and applied to the stream. The delay between each signal and charge corresponds to the time it takes the cell to move from the laser beam to the point where the drops break off. Thus, an appropriate charge is given to the drops containing fluorescent cells as they break off from the stream.

The drops then pass between two statically charged deflection plates and are deflected to appropriate containers.

"By using this instrument, we can look at up to 10,000 cells per second and separate up to 2,000 fluorescent cells per second," Sweet said. "In a typical experiment, we can separate a sample containing 50 million cells into two fractions containing fluorescent and non-fluorescent cells."

The research has been supported in part by the National Institutes of Health and in part by the National Aeronautics and Space Administration.

STANFORD -- A computerized system to efficiently store, retrieve, and disseminate bone marrow examination reports has been developed at Stanford University Hospital.

The new system enables medical personnel, using conversational language, to obtain information from patient files without any programmer intervention.

Development of the system was announced Thursday, October 28, at the annual meeting of the American Society of Clinical Pathologists in Boston, Massachusetts. Authors of the Stanford report were Dr. Herbert R. Ludwig and Dr. Jacques F. Vallee of the Stanford Computation Center, and Dr. Paul L. Wolf, associate professor of pathology and director of clinical laboratories at the University Medical Center.

Stanford is one of the few hospitals in the country which utilizes a computer for the storage and retrieval of bone marrow data.

The Stanford system is based on a new computer program called CUPID (Create, UPdate, Interrogate and Display), developed by Ludwig. It can be operated by anyone without previous experience in computer programming.

"Our system is unique in that the retrieval of pertinent information can be accomplished in an interactive, non-procedural mode," Ludwig said. "The physician, medical technologist, or secretary can talk to the computer directly and give it commands in natural, conversational language. There is no need for an experienced computer operator."

By using CUPID, Ludwig said, the physician is provided with essential information on three levels: the standard clinical diagnosis, an improved bone marrow report (permanently available for checking and editing), and a conversational retrieval and display language capable of answering unpredictable questions.

The new system solves a problem faced by many hematologists and pathologists in major medical centers, Wolf said. The expanding volume of bone marrow examinations performed has made it difficult to efficiently store and quickly have access to pertinent patient information essential to the diagnosis, treatment, and research of blood disorders.

STANFORD –

A group of scientists from Stanford University School of Medicine has found new clinical evidence showing that the kidney disturbance sometimes associated with methoxyflurane, a commonly-used inhalation anesthetic, is due to the amount of fluoride it contributes to the blood.

Fluoride is a major breakdown product in the metabolism of methoxyflurane. Recent animal work done by Stanford researchers in the Department of Anesthesiology and at Palo Alto Veterans Administration Hospital has shown that injections of fluoride produce abnormalities in kidney function similar to those seen after methoxyflurane is administered to patients.

In patients, the anesthetic appears to interfere with regulation of water in the body. Some excrete abnormally large quantities of urine due to failure of the kidney to conserve body water in the normal manner. In addition, abnormalities in blood chemistry result.

The findings were reported Tuesday, Oct. 19, at the American Society of Anesthesiologists meeting in Atlanta by Dr. Michael J. Cousins, acting assistant professor of anesthesiology, Dr. Richard I. Mazze, assistant professor of anesthesiology, and Dr. Tadashi G. Nishimura, resident in anesthesiology.

The investigators reported on a study designed to determine whether methoxyflurane could be administered at low dosage levels without producing kidney disturbance.

"Since fluoride is a breakdown product of methoxyflurane, and the kidney disturbance appears to relate to the amount of fluoride in the blood, the degree of kidney disturbance probably, in turn, relates to the total amount of anesthetic given to the patient," Cousins said.

The opportunity to test the theory came in the study of patients having heart surgery. Since they are very ill, they must receive relatively small doses of anesthesia, The study involved 20 male patients undergoing cardiac valve replacement or coronary artery bypass surgery. Ten of the patients received methoxyflurane and oxygen and a control group of 10 received intravenous morphine. Extensive laboratory tests of kidney fundtion were obtained on all patients before and after anesthesia.

Results of the study showed no differences between the two groups. Low dosage methoxyflurane anesthesia, for open heart surgery, did not cause abnormal kidney function. Clinically, all patients did well.

However, as expected, those patients receiving methoxyflurane showed 30-fold increases in their blood fluoride levels. However, the levels were only one-half those at which minor abnormalities in kidney function were seen in a previous study and one-fourth those at which more major symptoms of abnormal kidney function were previously detected.

"Although heart surgery represents a very specialized situation," said Cousins, "the results of the study may have generalized applications. The effects of fluoride ion on the kidney in these patients are probably not substantially different than those found in general surgical patients.

"The results support the hypothesis that methoxyflurane renal dysfunction is a dose-related phenomenon not occurring under the low-dosage conditions of the present study. Thus, it seems likely that if methoxyflurane anesthesia can be administered in carefully controlled low dosage, increases in fluoride ion will not be of a magnitude to result in abnormal kidney function. Studies are continuing to define these levels precisely."

It is of interest, Cousins notes, that the amounts of fluoride present in patients with kidney disturbances are at least 100 times those produced by drinking fluoridated water.

STANFORD -- Dr. Eugene D. Robin, professor of medicine and physiology, has been named acting chairman of the department of medicine at the Stanford University School of Medicine, Dean Clayton Rich announced Friday (Oct. 15).

The 52-year-old Robin, an expert on pulmonary disease, will succeed Dr. Halsted Holman who relinquished his administrative duties to return to research and teaching. Dr. Holman, Berthold and Belle N. Guggenhime Professor of Medicine, served as department chairman since 1960.

Dr. Robin came to Stanford in 1970 from the University of Pittsburgh where he had been professor since 1963 and associate professor since 1959. Previously he was associate director of the cardiovascular training program at Peter Bent Brigham Hospital in Boston.

At Stanford, Dr. Robin has supervised the respiratory function laboratory and the pulmonary physiology program.

He is a member of the board of trustees of the Mt. Desert Island Biological Laboratory, Salisbury Cove, Maine. He obtained his degrees at George Washington University: S.B. 1946; S.M. 1947; and M.D. 1951.

Last spring, Dr. Robin was one of the faculty recipients of the Henry J. Kaiser Award for excellence in teaching.

FOR RELEASE SUNDAY, OCT. 17 A.M.

STANFORD — Heart patients with a high risk of developing coronary heart disease can now be monitored during their daily activities by cardiologists at Stanford University Medical Center.

The monitoring device is a small tape recorder unit, worn by the patients, which continuously records electrocardiograms.

The taped electrocardiograms, analyzed by computer, enable Stanford cardiologists to detect abnormalities in cardiac rhythm which could later lead to a fatal cardiac arrest. If such abnormalities are found, the patient is given anti-arrhythmic drugs.

The new long-term monitoring program was announced Saturday night, Oct. 16, at the American Society of Anesthesiologists meeting in Atlanta by Dr. Donald C. Harrison, chief of the Cardiology Division at the Stanford School of Medicine. "Sudden death is frequently the initial manifestation of coronary heart disease," Harrison said. "However, I believe many of these patients have electrocardiographic changes of abnormal rhythms prior to the fatal arrhythmia resulting in sudden death.

"If such abnormalities in cardiac rhythm are detected, the prophylactic administration of anti-arrhythmic drugs may reduce the incidence of sudden death."

The Stanford monitoring system was developed in an attempt to determine how frequently these premonitory signs of impending disaster can be detected, Harrison said. Once it is possible to detect abnormalities which signal the possibility of a fatal arrhythmia, appropriate treatment for their prevention may be developed.

The program has been applied to patients who are in the susceptible age (45-60) for sudden death through coronary heart disease, whenever high risk patients can be identified. Such patients include those with severe chest pain or pressure, fleeting episodes of palpitation or other subjective symptoms suggesting arrhythmias, and episodes of dizzy spells.

The patients to be monitored are equipped with small recorder units, consisting of a portable tape recorder in a carrying case with shoulder strap, three small electrode discs attached to the patient's chest, and three wires leading from the electrodes to the recorder.

The analog tapes in the unit can record electrocardiograms for a period of 10 hours, while the patient carries on his daily routine.

Patients are asked to keep a record of activities and time on a log sheet throughout the 10-hour period. At the completion of the testing program, they return the tape recorder unit and log sheet for interpretation by cardiologists.

Computer scanning devices for analyzing the cardiac rhythm recorded on the tapes and for determining the occurrence and frequency of abnormalities have recently become operational at Stanford. By comparing heart action with the written log sheets, cardiologists can relate the occurrence of abnormal rhythms to specific activities the patient undertakes each day.

If a pattern of frequent or increasing cardiac changes emerges, cardiologists attempt to determine the likelihood of a fatal episode, and whether preventive steps should be taken.

Coronary heart disease affects between 10 and 12 million Americans and is the leading cause of death in the U.S.

STANFORD -- Stanford University surgeons performed a heart transplant operation late Wednesday night (Oct. 13). The recipient is a 48-year-old man. He is reported to be in satisfactory condition.

Including the new recipient, 14 of the 35 heart transplant patients operated on at Stanford are now living. Albert LeFleur of Fresno, 52, who received a transplanted heart on August 18 and was the 34th recipient, died Friday, October 8.

In accordance with a new policy announced by Stanford University Hospital in May, the new recipient's name has been withheld.

STANFORD -- Dr. Halsted R. Holman, chairman of the department of medicine at Stanford University School of Medicine since 1960, has relinquished his executive responsibilities.

The announcement was made Tuesday by Dean Clayton Rich, who said Dr. Holman had offered his resignation, and he had accepted it.

Dean Rich said he would appoint an acting chairman in the next few days until a successor to Dr. Holman is selected.

Dr. Holman will continue his teaching, research and patient care duties as Berthold and Belle N. Guggenhime Professor of Medicine, an endowed professorship he has held since his arrival at Stanford.

In accepting Dr. Holman's resignation, Dr. Rich wrote:

"I appreciate the high integrity behind this offer, and I am aware of the many excellent strengths of your department. I have spent a great deal of time considering this matter and conclude that it is in the long-range interest of the School to have rotation of executive leadership after so long a period under one chairman.

"This is particularly important for a department of medicine because of its key role in the entire program of the School."

Dr. Holman came to Stanford 10 years ago from the Rockefeller Institute. He is the son of two renowned Stanford physician-teachers, Dr. Emile Holman and Dr. Ann Purdy of San Francisco.

His major field of interest is the immunology of rheumatic diseases and tissue transplantation. He is recipient of the Walter Bauer Memorial Award for Research on autoimmunity presented by the Arthritis and Rheumatism Foundation in 1964, and a past president of the Western Association of Physicians and the American Society for Clinical Investigation.

During the past year, Dr. Holman has participated as chairman of a Medical School's special subcommittee to explore ways and means of providing health services for a given community on a pre-paid basis.

ADVANCE FOR RELEASE OCTOBER 13, 1971

STANFORD -- Thirty doctors, technologists and students are attending a two-day workshop on the use of automated laboratory equipment Wednesday and Thursday (October 13 and 14) at Stanford University Medical Center.

The participants, from the Hospital and the School of Medicine, are learning how to operate auto analyzers, which can perform a variety of chemical analyses. They are made by Technicon Corporation of New York, sponsors of the workshop.

The analyzer is a series of interconnected modules that automates the time-consuming procedures of manual analysis in the laboratory. Basic clinical tests, such as blood counts or coagulation factors, enzyme levels or hormone analysis, can be done in a matter of minutes. Only a very small quantity of sample is necessary.

Such equipment is an asset to patient care, explained Lisa von der Muehll, teaching supervisor at the Hospital's School of Medical Technology and Stanford coordinator for the workshop. Test results can be obtained rapidly and efficiently, an aid to the patient and his physician, she said.

Although analyzers are expensive, the cost per test is very low so that expenses are kept down for both the patient and the laboratory, according to Miss von der Muehll.

The clinical laboratory at Stanford University Hospital has several auto analyzers. The purpose of the workshop is to train additional medical and laboratory personnel and students in the uses of analyzers.

ADVANCE FOR RELEASE THURSDAY, OCTOBER 14, 1971

STANFORD -- Nurses and female anesthetists who work daily in hospital operating rooms contaminated with trace amounts of anesthetics are exposed to a potentially serious health hazard, a Stanford University medical research team warned Thursday (October 14).

Chronic exposure of operating room staffs to low-grade anesthetic pollution may cause miscarriage in pregnant women, the researchers reported.

Their study calls on hospitals to initiate measures as rapidly as possible to reduce this operating room contamination.

The Stanford research was initiated because several recent studies have called attention to the presence of trace concentrations of anesthetic gases in the operating room environment, and indicated a potential hazard to personnel. Until recently these trace amounts of anesthetics were considered harmless. Precise measurements of anesthetic contamination in the operating room had not been made.

Dr. Ellis N. Cohen, Dr. J. Weldon Bellville, and Dr. Byron W. Brown based their two-part study on personal interviews with 67 operating room nurses and 92 general duty nurses in three large hospitals in Northern California and on a mail questionnaire sent to 50 anesthetists and 81 female physicians practicing in other specialties.

"Results indicate that during a five-year period, 29.7 per cent of pregnancies in operating room nurses ended in spontaneous miscarriage compared with 8.8 per cent in the control group," the researchers reported in the October issue of Anesthesiology, a medical journal.

The increase in spontaneous abortion was even more significant among physician anesthetists who receive a greater exposure to anesthetics than nurses, the report shows.

In a six-year period the miscarriage rate among the physician anesthetists was 37.8 per cent compared with 10.3 per cent in the other female physicians.

Operating room nurses and anesthetists suffered miscarriages earlier compared with their controls (eighth versus tenth week).

These findings, according to the researchers, are especially significant in view of animal studies which show that chronic exposure to small concentrations of certain anesthetics is lethal to the fetus.

Cohen and his associates are careful to point out that showing a relationship between employment in the operating room and a significant increase in the incidence of spontaneous abortion is no proof of causation, but they have tried to examine common factors between the control and exposed groups.

In a companion report in the same journal, Stanford researchers Charles E. Whitcher, Ellis N. Cohen, and James R. Trudell reported their measurements of the level of exposure to certain anesthetics in operating room staff.

They determined the concentration of the anesthetic, halothane, and found a marked increase throughout the day.

As one would have predicted, the levels of exposure were much higher for physician anesthetists than for the nursing staff. This was precisely the same direction of increase as occurred in the incidence of spontaneous abortion in those two groups.

The Stanford researchers point out that more work needs to be done, "but until this is proven or disproven, all volatile agents present in the operating room must remain suspect," they said.

"Total elimination of all waste anesthetic gas is the goal, and should be attainable," Cohen said. "In the meantime, we recommend that all possible corrective measures be initiated."

One such measure involves installation of a "scavenging system" in connection with anesthesia equipment. The system, developed by Whitcher and his associates, captures overflow gases during normal administration of anesthesia, and vents them out of the operating room.

Stanford University Hospital was the first to install this device, Whitcher reported, and operating room contamination has been reduced to about 10 to 15 percent of that previously measured.

Commenting on the Stanford research, a journal editorial calls for an extension of the Cohen-Bellville-Brown studies to the field of public health in general.

"These findings are potentially more far reaching than operating room staff and raise the question of exposure to volatile agents during pregnancy," the editorial said.

Questions raised by the study include: "Does this danger extend to women exposed to anesthetics during surgery? What are the possible effects of other volatile agents, spray paints, hairsprays and air fresheners when widely used?

The editorial also stressed the need for studies to determine if anesthetics and other agents cause birth defects.

FOR IMMEDIATE RELEASE

STANFORD -- Dr. Robert H. Alway, former dean of the Stanford University School of Medicine, has been appointed to act as chairman of the department of pediatrics.

Dr. Clayton Rich, vice president for medical affairs and dean of the medical school, said Dr. Alway had agreed to accept the acting chairmanship at a crucial period during which the School is planning to undertake a re-examination of its goals.

He said a search committee for a new chairman would be appointed. It would have a dual charge of reviewing the future of pediatric training at Stanford and in a national context.

Dr. Alway, 57, succeeds Dr. Herbert C. Schwartz, who resigned to return to teaching, research and patient care duties. Dr. Schwartz headed the department for the past two years.

As dean of the medical school from 1957 to 1964, Dr. Alway was responsible for the successful relocation of the school from San Francisco to the campus, and recruitment of faculty which helped establish Stanford as a leader in medical education.

Dr. Alway, professor of pediatrics, will continue to direct the Stanford pediatric clinic.

He holds degrees from the University of Minnesota, and received graduate training in pediatrics from the same institution in 1940.

STANFORD -- An updated handbook that advises college undergraduates how to prepare for a career in medicine has been published by the Stanford University Premedical Society.

The handbook, newly revised this year, includes information for premedical and predental students on planning courses to meet the requirements of medical schools, selecting and applying to medical schools, and obtaining financial assistance. It was prepared by members of the Premedical Society under the guidance of faculty adviser Dr. Donald L. Stilwell, associate professor of anatomy in the School of Medicine.

Comprised of five sections, the booklet summarizes the experiences of medical faculty advisers and generations of students. An introduction by Dr. Stilwell stresses that "any field is compatible with medicine."

The section on academic curriculum lists specific science courses at Stanford that pre-medical and dental students should follow, but suggests schedules arranged to allow for a variety of nonscientific interests, including overseas study.

This section points out that although certain science courses are necessary, a student does not have to be a science major to be accepted by a medical school. "Medical schools are not interested in a narrow-minded person. They tend to look for people who have a diversified education".

Another section on the application process provides helpful hints on meeting various admission criteria of most medical schools. In addition to the individual's college transcript and scores on the medical college and dental admission tests, schools weigh such factors as recommendations, extracurricular activities and personal interviews.

"One of the most revealing of all criteria" according to this section, is the personal statement required on most medical school applications. "This 'self-recommendation' ought to be a subjective instrospection of goals, personal values and strengths, and an examination of oneself in medicine."

The purpose of the Stanford Premedical Society, explains president Burr Field, is to bring students interested in medicine or health-related fields together in a relaxed situation outside the classroom. The Society, which this year has 125 members, arranges programs during the year to expose its members to the diverse medical opportunities through personal contact and participation.

The handbook is available at Stanford at the Academic Information Center, and is also being distributed to premedical societies of other universities.

STANFORD -- A recent disclosure by a group of students and staff that Stanford University School of Medicine will build a multimillion-dollar cancer center is "premature and misleading," a Medical School official said Tuesday.

"The School is only exploring the idea and has applied to the federal government for a $200,000 planning grant," said Robert G. Lindee, associate dean for administration.

The grant, according to Lindee, will enable the School to study the feasibility and desirability of expansion of the present radiotherapy center into a more comprehensive facility involving other departments engaged in cancer research.

"Only if expansion of the present center is deemed feasible and desirable, the School will undertake detailed planning," Lindee said.

He stressed the initial study will consider not only the scope and organizational aspects of the proposed center, but its impact on the goals and structure of the Medical School and the University.

He added that no one at this time could guess how much such a project would cost. It would be sheer speculation.

Lindee made the clarification because a statement, issued Monday by 22 medical students and staff, claimed that the Medical School is proceeding with development of a $20- to $30-million cancer research center "without regard for any real need for additional beds or services," and no discussion with those affected.

Lindee added, even if development of a cancer center went on independently, it would in no way interfere with other programs the Medical School may wish to develop in other areas.

In a separate statement, Thomas Raffin, co-president of the Stanford Medical Students Association, said he believes that a cancer center could be of great value to Stanford and the surrounding communities. "But it is important to carefully evaluate the effect that such a center might have on the future direction of Stanford Medical School, and on its role in the delivery of health care in this region," he added.

STANFORD -- Dr. Karl H. Pribram, professor of neuropsychology at Stanford University School of Medicine, has been appointed to the Behavioral Sciences Training Committee of the National Institute of General Medical Sciences.

The Institute is a component of the National Institutes of Health (NIH).

According to Institute Director Dr. DeWitt Stetten, Jr., Dr. Pribram and other committee members will review applications for research training grants. They will also advise the Institute on the development of training programs in modern research techniques in the behavioral sciences.

An internationally noted neurophysiologist, Dr. Pribram has been exploring the mysteries of the brain--how it records, stores and retrieves information--for two and a half decades.

Author of numerous publications, he is editor of 10 volumes and co-author of Plans and the Structure of Behavior. His most recent book, Languages of the Brain, was published a month ago.

Dr. Pribram came to Stanford in 1959 after 10 years on the faculty of Yale University. He was appointed to his present position in 1961, the same year he was awarded a lifetime research grant from the NIH.

STANFORD -- "I send nearly as many patients to the library as to the drugstore," says Dr. Louis Shattuck Baer. "Often patients will leave my office with a list of recommended readings instead of a prescription."

Dr. Baer is a proponent of what he calls "philosophic therapy," a meditative, or humanistic approach to the treatment of patients. A specialist in internal medicine, he has been putting his theories to practice while treating patients in his Burlingame office for the past 25 years.

"Almost 30 years as a family physician have taught me that the precepts of philosophy surpass medicine or surgery as therapy for many of my patients," he says.

"I think the emphasis on scientific analysis and treatment of patients in many ways has burgeoned to the detriment of the meditative approach. From the standpoint of a family doctor, I feel this often has not beenin the patients' best interests."

In an effort to get his views across to the medical community, Baer is offering six one-hour seminars (free of charge) at the Stanford University School of Medicine this fall. The seminars, dealing with topics such as "The Necessity of Suffering," will be held in Medical Center Room M104 from 4:30 to 5:30 p.m. on six successive Wednesdays beginning October 13. They are also open to the public.

"There frequently is not enough time in the regular medical program for a consideration of the philosophic implications in both diagnosis and treatment," Baer says. "So many of our diagnostic methods today are invasive, and these methods often are more dangerous to the patient than what's bothering him in the first place.

"The scientific aspects are weighted too heavily--after all, we're in the atomic age. I'm just trying to keep the scales more evenly balanced. The more human aspects of medicine can't be ignored. As Montaigne said, 'we do not feel perfect health as well as we feel the slightest illness.' "

Baer doesn't recommend philosophic therapy for every patient. The value of the meditative approach comes in the treatment of a patient whose state of mind is related to, or even partially responsible for, his problem.

"Philosophy is not necessary for the average patient who comes to see a physician," Baer points out. "Where philosophy becomes important is in treating the patient who has a chronic illness he must live with or an illness which will be fatal.

"It's also valuable in dealing with the patient who's worried to the extent that it's making him sick, and the patient who's run out of hope, who sees his case as hopeless."

Others who might benefit from a meditative approach to their problems, he says, include unhappy and unthankful patients, who "look at their own problems too microscopically."

-more-

Baer contends that suffering is not inevitable, but necessary to man's existence. He regards it as a foundation or cornerstone of reality.

"It's my belief that suffering is as necessary as oxygen, nitrogen or carbon for man's origins, his evolution and his continued existence," he says. "If this is understood, then perhaps we can seek to mitigate it with better proportions of calculative and meditative thinking than is seen in the practice of medicine today."

Baer first began thinking about philosophic therapy 20 years ago when he was stricken with polio.

"I was out of the picture for a year and a half," he says. "It was a very severe attack which changed my whole life. It gave me time to think of myself as both a doctor and a patient.

"For the next 10 years I did a lot of reading--mainly the philosophers. I only started writing the material for these seminars on the beach at La Jolla 10 years ago. I've been cooking it, doing a lot of re-writing, since then."

Baer, a clinical associate professor of medicine at Stanford, received his M.D. from the University of Chicago in 1938. He served his residency at the University of Michigan Hospital, then was a lieutenant commander in the U.S. Navy Medical Corps for four years. He entered private practice in Burlingame and joined the Stanford clinical staff in 1946.

STANFORD -- A new class of physician is being trained at Stanford University Medical School. Called a clinical scholar, the new physician will prepare for a career in the economical, social, administrative, or educational aspects of medical care delivery.

Stanford is one of five medical schools that has begun training clinical scholars in order to bridge the gap between the medical scientist and the community. Once trained, these scholars will research, develop and conduct new forms of health delivery programs and staff related training programs for other physicians and health personnel.

The programs at the medical schools--Stanford, Case Western Reserve, Duke, Johns Hopkins, and McGill--are being supported by grants from the Carnegie Foundation and the Commonwealth Fund of New York. Stanford Medical School has a two-year grant of $96,000 for the training of up to six clinical scholars through the Department of Medicine.

"The development of a good medical care delivery system requires a combination of biological and nonbiological sciences," said Dr. Halsted Holman, professor and chairman of the Department of Medicine. "At present the nonbiological aspects are a severely underdeveloped area of medicine," he continued.

Physicians today are trained for research in the pure sciences or for practice in the community, Dr. Holman explained. Neither group of physicians, however, study the organization or administrative aspects of the medical care system of which they are part.

Clinical scholars will study and investigate clinical practice and nonbiological areas of medicine in a manner analogous to the medical scientist. They may be concerned with developing new methods of medical care, setting up community health programs, supervising community hospital clinics, conducting clinical investigations within the community or evaluating and reorganizing clinical education.

Stanford Medical School has two clinical scholars this year. They are Dr. Raymond LaSure, a fellow in medicine and Dr. Edwin Alderman, an instructor in medicine. Dr. LaSure is developing mechanisms for estimating the quality of medical care delivery and the potential of future health plans. Dr. Alderman is concentrating on the handling of medical information, and is a consultant on a Stanford-NASA biomedical technology team.

The clinical scholars training program is one of several projects worked out by the five medical institutions during the last two years under a prior grant from the foundations to experiment with methods of improving graduate and continuing education for physicians and strengthening ties between medical schools and communities.

Faculty members in the Department of Medicine responsible for the program at Stanford include Dr. Edward Rubenstein, chairman of the committee on postgraduate medical education; Dr. Mark Perlroth, assistant professor and program director for the experimental training program, and Dr. James Fries, assistant professor and former clinical scholar in the experimental program.

HEART TRANSPLANT #10, SASHA GILIEN, Transplant 2/8/69

DIED NOV. 29, 1971

BUSINESS WIRE

11/30/71 2:00 p.m.

FOR FURTHER INFORMATION CONTACT: Gary Cavalli or Hali Wickner 415: 321-5310

STANFORD -- Sasha Gilien, Stanford University's second longest surviving heart transplant patient, died suddenly at his home in Santa Cruz Monday night (Nov. 29).

Doctors at Stanford Hospital said Gilien died of a heart attack, although final autopsy reports are not yet available.

Gilien, 46, received a new heart at Stanford University Hospital February 8, 1969, after suffering a near fatal attack January 20. He was the tenth heart transplant patient operated on by Dr. Norman Shumway and his surgical team.

A free lance writer in Los Angeles for several years prior to his operation, Gilien recently moved to Santa Cruz , where he continued his writing career.

He authored several television scripts, including an episode of "Hawaii Five-O" starring Nancy Wilson which was honored by the annual Writer's Award Banquet in Los Angeles.

Gilien was co-author of the popular "The Begatting of a President" which sold more than 200,000 copies and was released on a record narrated by Orson Welles. The recording was nominated for a Grammy award for "Best Comedy Record of the Year."

Recently, he co-authored a sequel, "The Begatting of a Revolution" and wrote a television script "The Dream Boys" which American Broadcasting Company bought for a movie.

Of the 37 heart transplant recipients operated on at Stanford, 15 are now living. Carl P. Sheaffer, Stanford's longest surviving transplant patient, received a new heart on Oct. 26, 1968.

STANFORD -- Stanford University has announced plans to establish an outdoor primate facility for behavioral research and teaching on the northwest corner of Webb ranch.

An application for a land use permit was filed by the University with the San Mateo County Planning Commission Wednesday (Nov. 24).

A public hearing to review Stanford's application will be held in Redwood City December 15.

The land involved is 26 acres, located west of Interstate Route 280 at the meeting point of the Stanford Linear Accelerator and Jasper Ridge, the University's biological preserve.

The proposed open-field outdoor primate facility will be at the center of the 26-acre site on six acres of land. The fenced facility will house 10 to 40 young chimpanzees. A centrally located two-story observation center for up to 12 persons will be built. The first floor will serve as a shelter for animals, and as a feeding point. The structure will be about 2,200 square feet.

Stanford's application states that the facility will be far removed from residential areas. "It will have double fencing which will prevent escape of the animals as well as intrusion from unwanted visitors. An alarm system will be installed on the outer perimeter fence as an extra precaution."

In addition, the University plans to landscape the area for further isolation. The observation building and a portion of the fence in the main compound are designed to blend with the surroundings.

Prior to designing the facility, members of the department of psychiatry and the resident architect's office in the Medical School toured other outdoor animal centers around the country, and have incorporated key safety features in the planning.

Construction of the facility has been made possible by a grant from the Grant Foundation of New York. Stanford hopes to begin construction in Winter, with completion anticipated next Spring.

Research in primate behavior will be directed by Dr. David A. Hamburg, professor and chairman of the department of psychiatry, and Dr. Jane van Lawick-Goodall, a visiting professor of psychiatry at the Medical School, and a pioneer in studies of chimpanzee behavior.

-more-

Primate Facility

222

The program is part of a broader University-wide study of the problem of human aggression and violence.

One of the researchers, Dr. Keith Brodie, assistant professor of psychiatry, said the facility will serve as an observation point of the natural behavior of chimpanzees.

"We will begin our observations with 12 animals, and build up slowly to a maximum of 40," he said. "Our initial studies will be on the adaptation of these chimpanzees to their new environment.

"About a year after arrival, the first signs of puberty in these animals should become evident, and we will then focus on the changes of behavior that occur during adolescence."

Brodie said that in recent years biomedical research has turned increasingly to man's closest relatives--monkeys and apes--to explore in depth the possible causes, treatment and prevention of many human disorders.

"Ultimately, such studies tell us where to look for crucial points of vulnerability. They permit us to examine relations of biology and behavior that are impossible to study in man, at least until they have been worked out in primates," he said.

Recent animal studies, however, have suffered from one major limitation--the nature of conventional laboratory facilities, according to Brodie. These studies, to a large extent, have been limited to animals housed in cages, and have been analogous to studying the behavior of man imprisoned in solitary confinement.

"Therefore, we view it as extremely desirable to have this experimental facility that combines features of the laboratory and natural habitat," Brodie said.

Heart Transplant Patient #37, Transplant #38

STANFORD -- Stanford University surgeons performed a heart transplant operation late Saturday night (Nov. 20) on a 49-year-old California man. He is reported in satisfactory condition.

Including the new recipient, 16 of Stanford's 37 heart transplant patients are now living.

In accordance with a new policy announced in May, the new recipient's name has been withheld.

AN OUTDOOR PRIMATE FACILITY AT STANFORD

To answer inquiries from interested citizens, the Stanford Medical Center News Bureau interviewed Dr. Keith Brodie, assistant professor of psychiatry. Here he describes the work and purposes of the proposed outdoor primate facility at Stanford University, and answers questions related to construction and selection of the site.

Q: Where will the primate facility be located?

A: The facility will be located on a remote area of Webb Ranch, west of Route 280 at the meeting point of the Stanford Linear Accelerator and Jasper Ridge, the University's biological preserve. The land, which forms a small basin, is one of several sites considered. It was picked because it is out of view, and far removed from residential areas. It is also free from neighboring facilities, and relatively inaccessible to uninvited visitors, children, and stray animals. The land involved is 26 acres which will be enclosed by a secondary, eight-foot cyclone fence. The proposed primate facility will be located at the center of this buffer zone on six acres of land.

Q: What is the purpose of Stanford's primate facility?

A: Basically, we view this facility as a tool which will enable us to observe the natural behavior of chimpanzees. In recent years biomedical research has turned increasingly to man's closest relatives--monkeys and apes--to explore in depth the possible causes, treatment and prevention of many human disorders. Ultimately such studies tell us where to look in man for crucial points of vulnerability. They permit us to examine relations of biology and behavior that are impossible to study in man, at least until they have been worked out in primates. Recent animal studies, however, have suffered from one major limitation--the nature of conventional laboratory facilities. Because these studies have been, to a large extent, limited to animals housed in cages, they have been analogous to studying the behavior of man imprisoned in solitary confinement. Therefore, we view it as extremely desirable to have an experimental facility that combines features of the laboratory and natural habitat.

Q: What kind of animals will be housed in the facility?

A: We are interested in studying chimpanzees, under six years of age. When the facility is built, we will begin our observations with 12 animals, and build up slowly to a maximum of 40. Our initial studies will be on the adaptation of these chimpanzees to their new environment. We will be interested in their ways of exploring the new habitat, the mode of transmission through the group of new habits, and the ways in which their behavior differs from that in the old habitat. About a year after arrival, the first signs of puberty in these animals should become evident, and we will then focus on the changes of behavior that occur during adolescence.

Q: What will the primate facility look like?

A: As I mentioned, a six-acre escape-proof enclosure is contemplated, surrounded by a 20-acre buffer zone for isolation. The fence designed to contain the animals will be 15 feet tall. The upper portion of the primary cyclone fence will be sheet metal, sloping inward to prevent animals from climbing over it. The compound will be circular and will be divided into four sections or pens. A central two-story observation center for 12 people will be the only building on the site. The first floor of this building will serve as a shelter for animals, and as a feeding point. The structure will be about 2,200 square feet.

-more-

Q: Do you anticipate any instances where some chimpanzees may escape?

A: First, six acres of land are rather a large area and provide ample freedom for animals to roam around. Second, chimps like to stay close to each other and find it unattractive to leave the group. Third, there will be a back-up protection if an animal manages to leave the compound. The secondary fencing system around the 26-acre perimeter will be equipped with an alarm or electronic guard connected to the security office. In other primate centers we have studied across the country, animals leaving the compound and causing damage to property or humans was not cited as a problem. Our major concern in taking these precautions is to prevent theft and vandalism and to keep unwanted persons from entering the area.

Q: Is there any work done elsewhere that is similar to this Stanford project?

A: No. Other primate centers have focused their efforts primarily on the medical aspects of chimpanzee research. For example, the problem of chimp resistance to viruses and antibody production. The chimp approximates the human in the sense of the number of chromosomes and certain of the blood proteins. Basically, no group has done the basic ethological observations we plan to undertake at Stanford.

Q: Can this work be done in Africa? Why Stanford?

A: This is a good question. The most important problem, of course, is an economic one. It would be very costly to assign researchers to a laboratory in Africa. There are advantages to having this facility here for several reasons: It is closer to our research laboratories where we plan at first to study urine specimens from these animals to observe metabolic changes. We also view the outdoor primate facility as a major center for research training, and for arousing interest among students in the scientific study of behavior. For example, during the past academic year no single subject has elicited so much interest among human biology students at Stanford as this topic. The human biology program is taught by several departments and deals with man as a biological organism in relation to his changing environment.

Q: What about the aesthetic appearance of the observation building and fences?

A: This question implies that someone will be there to look at the building. Actually, we have done tests and found that only a few homes in Ladera have eye contact with the proposed site. The distance between these homes and the site is 1-1/2 to 2 miles, and will present no problem. We plan to take steps to eliminate objectionable glare from the sheet metal of the primary fence. Earthy colors similar to the SLAC buildings will be used to make this facility blend with the surroundings.

Q: Do you plan any landscaping?

A: Yes. We will plant eucalyptus trees and other fast growing vegetation to screen the facility and to provide further isolation.

Q: Do you know if noise in such a primate facility is a problem?

A: The primate facility at Tulane University is within three blocks of a residential area. We inquired about noise and we were told there is no problem. Stanford's proposed primate center is farther away from residential areas and we do not see a noise problem arising either.

-more-

Q: In your studies, do you plan to use drugs, surgery, or other manipulative techniques?

A: No. Our work will be simply to observe these animals and record their behavior in a natural environment.

Q: Who is funding construction of the primate facility?

A: Construction is made possible by a grant from the Grant Foundation of New York.

Q: Who will direct the research?

A: The research will be done under the direction of Dr. David A. Hamburg, professor and chairman of the Department of Psychiatry, and Dr. Jane van Lawick-Goodall, a visiting professor of psychiatry at the Stanford Medical School, and known for her pioneering studies of chimpanzee behavior. Dr. Goodall will commute to Stanford from the Gombe Stream National Park in Tanzania, Africa twice a year for teaching and research responsibilities. Collaborators in the research will also include members of the departments of psychiatry, psychology, sociology, biochemistry, and statistics. The program is part of a broader University-wide study of the problem of human aggression and violence.

Q: What is the construction timetable?

A: We hope to begin construction in winter, and have the facility ready for occupancy in the spring.

STANFORD -- An all day workshop on the safe use of medical equipment will be held at Stanford University School of Medicine December 4, sponsored by the Association for the Advancement of Medical Instrumentation (AAMI).

It will present information for personnel responsible for patient care and instrument management on how to operate medical equipment safely. In particular, the workshop will discuss the proper use of electrical equipment to avoid accidental shock to patients or personnel, and the correction of existing problems.

Registration and information can be obtained through the AAMI office at 9650 Rockville Pike, Bethesda, Maryland 20014 (telephone 301: 530-2800). The tuition fee, which includes training materials and lunch, is $50 for members; $60 for nonmembers, and $20 for medical students, interns and residents. Physicians, nurses and engineers, and other interested personnel are welcome to attend.

The coordinators for Stanford are Drs. Alfred P. Spivack, director of Stanford University Hospital's Coronary Care Unit, and Dr. Delmar Snider, assistant professor of anesthesia. The session will be held in Room M106 at the Medical School from 8:30 a.m. to 5 p.m.

Advance registration should be made.

STANFORD--Dr. Thomas N. James, director of the Cardiovascular Research and Training Center at the University of Alabama in Birmingham, will deliver the eighth annual John Kent Lewis Memorial Lecture Monday, November 22, at Stanford University School of Medicine.

His speech, entitled "Diseases of the Large and Small Coronary Arteries," will begin at 4:15 p.m. in Room M106 at the Medical School.

Dr. James, also professor of medicine and pathology, and associate professor of physiology and biophysics at Alabama, has devoted over 20 years to the study of the heart. He has published nearly 200 papers and contributed to 13 books on many aspects of cardiology.

In 1961, Dr. James authored Anatomy of the Coronary Arteries, considered the outstanding book in the field. His most recent research has dealt with the effect of disease on the cardiac conduction system, and how this relates to sudden death.

A past vice-president of the American College of Cardiology, he was awarded the 150-year medal of the Swedish Medical Society in Stockholm in 1961.

A native of Amory, Mississippi, Dr. James received his M.D. degree in 1949 from Tulane University School of Medicine in New Orleans, Louisiana. Before assuming his present position, he served on the Tulane faculty and was chairman of the Section on Cardiovascular Research at Henry Ford Hospital in Detroit.

The John Kent Lewis Lectures are presented in honor of the former chief of the Stanford Medical Service at San Francisco General Hospital. Dr. Lewis was a 1922 graduate of the Stanford School of Medicine. A noted pioneer in heart research, he died in 1961.

STANFORD--

When the Mariner 9 spacecraft goes into its information-gathering orbit around Mars Saturday, Nov. 13, 4:31 PST, a team of Stanford scientists will begin analyzing data concerning variable features on the planet.

The basic objective of the Mariner 9 is to study the characteristics of Mars for a period of at least 90 days. Previous "flyby" missions (Mariners 4, 6, and 7) could make only spot checks of the planet, because they were in its vicinity for only a very short time.

Mariner 9 provides the first opportunity for lengthy orbital observation of Mars, and for analysis of data while the spacecraft continues to gather information. Thus, information from one orbital pass, processed at the Jet Propulsion Laboratory (JPL), Stanford and elsewhere, can be used to develop operations plans for the rest of the orbital passes.

Stanford Nobel Laureate Dr. Joshua Lederberg is one of five principal investigators in the television experiment, one of six orbital experiments to be conducted by Mariner 9. Dr. Elliott C. Levinthal, director of Stanford's Genetics Instrumentation Research Laboratory, is one of four co-investigators working with Lederberg.

The television experiment, perhaps the most significant of the mission operations, will include investigation of fixed and variable features of the planet. The fixed-features investigation will allow the mapping of 70 percent of the Mars surface in finer detail than is possible through telescopic observations or data from previous spacecraft.

The variable features investigation, the chief concern at Stanford, will provide information on daily, seasonal and time-variable changes in surface and atmosphere.

Stanford scientists are especially interested in the biological inferences which could be suggested by data from Mars.

"We'll be looking at this information to see what implications it could have for biological hypotheses about the planet," Levinthal said. "Generally, we believe Mars is very hostile to life. The television experiment probably won't provide direct evidence about the possibility of life on the planet, but rather an indication whether there are ecological niches which may be hospitable to biological life.

"The focus of our interest," he went on, "is looking for variable features. We've been designing methods of analyzing data so that surface changes are made apparent. Much of this work was done in our Artificial Intelligence Laboratory by a team which includes Prof. John G. McCarthy (computer science) and research associates Lynn Quam (computer science) and Robert Tucker (genetics)."

During the mission, digital data tapes will be brought to the Stanford Artificial Intelligence Lab for analysis by computer. The analyses will be sent back to mission headquarters at the JPL within a day or two.

Additional data obtained from the television cameras and other instruments on board the spacecraft will be processed at the JPL.

Together, these results will be used to make recommendations regarding possible changes in mission planning and operations throughout the 90-day period.

"Our concern is with data that can affect the mission," Levinthal said. "Decisions we make may change the spacecraft's operations a few days later. We can't anticipate where something interesting might turn up. If it does, and we'd like to take a better look at it, we can change our plans accordingly."

Levinthal and Lederberg have been working on the Mariner 9 project since October 1968. They are also involved in the research and planning of the Viking Mars exploration mission, in which an automated spacecraft will be landed on Mars. The present target date for the Viking launch is 1975, with the landing scheduled for '76.

Stanford School of Medicine's Genetics Instrumentation Research Laboratory was established nine years ago to design devices which can study the possibility of life on other planets. Techniques learned from the space program are being applied to the fields of biology and medicine.

Heart Transplant Patient #36, Transplant #37 November 8, 1971

FURTHER INFORMATION CONTACT: Hali Wickner 415: 321-5310

STANFORD -- Stanford University surgeons performed a heart transplant operation Monday afternoon (Nov. 8) on a 38-year-old man from New Berlin, Wisconsin. He is listed in satisfactory condition.

In accordance with a new policy announced in May, the Hospital does not usually release the name of the recipient. However, the Journal publishing company of Milwaukee, Wisconsin, where the recipient is employed as assistant foreman in the stereotype room, has revealed his identity. The Hospital has confirmed that he is Richard Mueller.

Including Mueller, Stanford's 36th heart transplant patient, 15 of those operated on here are now living. Stanford's longest surviving patient and seventh recipient, Carl P. Sheaffer, 57, of Winchester Bay, Oregon, recently celebrated the third anniversary of his new heart, which he received at Stanford on October 26, 1968.

FOR IMMEDIATE RELEASE
STANFORD –

The tall, attractive blonde seemed very much at home sitting behind a desk in the Department of Psychiatry at Stanford University Medical School. However, her real "home" is among the wild chimpanzees of East Africa.

Dr. Jane van Lawick-Goodall, visiting professor of psychiatry at the Medical School, has spent a good part of the past 11 years living among the chimpanzees of Tanzania. An internationally known researcher on chimpanzee behavior, she will commute to Stanford from Africa twice a year during the spring and the fall for teaching and research responsibilities here.

The rest of the year she will continue her work at the Gombe Stream National Park on the eastern shore of Lake Tanganyika, where she has been observing and recording the behavior of chimpanzees since 1960.

"The chimpanzee is a creature of immense significance to man," Dr. Goodall said. "In addition to being extraordinarily close to man in biochemistry and brain structure, the chimpanzee has striking behavioral similarities, particularly in his communicatory gestures and responses. We hope that research on the behavior of man's closest relatives will help man in understanding himself," Dr. Goodall explained.

The scientist said that she could not remember a time when she did not want to go to Africa to study animals. After she finished school in England, she worked to save up the fare to Nairobi where she had a temporary job. There, she met and worked for the noted anthropologist Dr. Louis Leakey. A year later, sensing the deep-rooted interest in the young English woman for the animals of the wild, Dr. Leakey asked her to undertake a field study of chimpanzees. He suggested that she use this research toward a doctorate in ethology [animal behavior] at Cambridge University, which Dr. Goodall received in 1965, and also helped her obtain the funds for the project.

Thus, with little experience in scientific observation, but a lot of spirit and enthusiasm, Jane Goodall set out to make camp among the apes of the Gombe Stream Park. The only area in Africa set aside specifically for chimpanzees, the Park is well suited for observation, according to Dr. Goodall, because of the treeless ridges and open spaces that are part of its 60 square miles.

Yet it took Dr. Goodall well over a year of daily observation, watching through binoculars and gradually moving in from the ridges, to even get close to the chimps. Her goal was to keep out of their social picture and be accepted as a piece ~~of the environ~~ment. At first the chimps were scared, then hostile and aggressive, but they never attacked her, she said.

After six months, Dr. Goodall could distinguish individual characteristics of various chimps, and as she got closer to them, their physical differences became more obvious. She began naming the chimps—Flo, Figan, David, Goliath, Passion, etc. Gradually, with courage and patience, Dr. Goodall won the confidence of these wild animals, many establishing themselves as regular visitors to her camp.

On the recommendation of Dr. Leakey, noted wildlife photographer Baron Hugo van Lawick joined Dr. Goodall in 1962 to film her work. The couple were married two years later.

Dr. Goodall's systematic studies of the chimpanzee in his own community have provided valuable insight into the behavior of both the chimpanzee and man, said Dr. David Hamburg, professor and head of the Department of Psychiatry at Stanford Medical School.

"Her research is unique because individual animals have been recognized and studied, because close range observations are accurately recorded, and because there is a superb photographic record made by Hugo," Dr. Hamburg said.

(more) 11/8/71

Drs. Hamburg and Goodall first met at a primate behavior conference in 1965. In 1968, they began planning joint research on aggressive behavior in nonhuman primates. Dr. Hamburg has visited the Gombe Park several times. He feels that Stanford's new primate center which is being planned to study chimpanzees in a habitat similar to their natural one will complement Dr. Goodall's research in Africa. Dr. Goodall will be a collaborator in research at the center.

With Dr. Hamburg, Dr. Goodall also lectures in human biology classes. This quarter she discussed the relevance of chimpanzee behavior to the study of man. It was her first teaching experience and she enjoyed it immensely, she said. Human biology is a series of courses which approaches biology from a multidisciplinary orientation to include all sciences related to biology. Dr. Goodall added that this concept of teaching biology is stimulating.

Since 1964, students have come to Africa each year to work with Dr. Goodall as research assistants. They usually have a bachelor's degree in one of the sciences, such as anthropology, psychology, zoology or physiology. "Such an interdisciplinary study of the chimps is necessary," Dr. Goodall explained, because there are so many facets to their behavior.

This year Stanford has begun a collaborative program with the African Observation center. Three students from the Gombe center will be working toward doctorates at Stanford. A selection of students from human biology will go to Africa as part of a new undergraduate training program there.

The assistants have enabled Dr. Goodall to maintain continuous, daily records that detail the behavior of these chimps as they range freely over their native hills and forests. The studies now encompass three generations of chimpanzees, having followed one mother and her young until the mother became a grandmother. "A shrunken, wizened old woman around 40, this grandmother is certainly the oldest chimp in our group," Dr. Goodall commented.

The British scientist has made contributions to the knowledlge of chimpanzee behavior that have altered man's concept of the primates and of himself. One of her most significant discoveries was that man is not the only species which makes tools. Dr. Goodall has watched chimpanzees fashion and use such simple tools as "fishing rods" to probe for termites in their mound, or "sponges" of partially chewed leaves to sop up drinking water they cannot reach with their lips.

Another "fascinating experiment" occurred in feeding the chimpanzees, Dr. Goodall explained. At first, anxious to lure the chimps into the camp, she would feed them bananas every day. But she noticed that during these regular feedings, aggression among the chimps had "skyrocketed" and the chimps would fight for bananas. She reasoned that the unnatural food source had altered normal eating patterns and had also attracted different groups of chimps that would not normally interact. Now, the chimps are not fed too frequently. The eating area is designed to simulate natural food sources and to stimulate as little aggression as possible. It consists of an elaborate trench system of sunken boxes which can be automatically emptied and filled from a main control inside one of the camp buildings.

Dr. Goodall is very excited about the affiliation of Stanford with Gombe in Africa. "It means that the research is taking the direction I've always wanted it to take, and that we will be making use of our understanding of chimpanzee behavior to understand man," she said.

She added that Gombe would not be functioning without Dr. Hamburg. "It is hard to sufficiently express my gratitude to Dr. Hamburg, not only for his aid in obtaining money from the Grant Foundation and the Commonwealth Fund of New York for us to continue in Africa, but for his inspiration, encouragement, and genuine interest."

Dr. Goodall has written several articles and books about life with the wild animals of Africa, and all include photographs taken by Baron van Lawick. The team's latest book, *In the Shadow of Man,* which has just appeared, is a personal, nonscientific chronicle of the rewarding years the couple have spent so far among the chimps.

Some years they spend more time than other years in Africa, because of lectures, meetings, and other commitments. However, Dr. Goodall said that beginning next year, with their four-year-old son, they will be living at the Gombe Stream Park "more or less permanently."

Reaching out to 11-month-old Flint, Dr. Jane van Lawick-Goodall extends the back of her hand to him--fingers turned away--to indicate she intends no harm. An internationally known expert on chimpanzee behavior, Dr. Goodall has lived among the chimpanzees of Africa since 1960. She will commute to Stanford University Medical Center twice a year as visiting professor of psychiatry.

STANFORD -- An improved technique of reconstructive hip surgery--developed in England and now introduced in the United States--is expected to help thousands of elderly patients walk again, according to a Stanford University orthopedic surgeon.

The technique is a modified total hip implant, using artificial joints of metal and plastic welded to the thigh bone and pelvis with a special bone cement.

Innovations in the old technique of hip surgery include use of a new type of bone cement, and a combination of metal and plastic protheses which simulate the hip socket and ball-like upper portion of the thigh bone.

The bone cement was approved in October by the federal Food and Drug Administration for use in orthopedic surgery in this country. It is called Simplex P and consists of an acrylic polymer.

In describing the technique at recent meetings of the California chapters of the American Physical Therapy Association in Oakland and Newport Beach, Dr. David S. Burton said he would have little hesitation in advising this form of surgery to older patients who cannot walk without canes or crutches, who are unable to work, and who have severe pain.

"The operation," however, "is definitely not for the patient with an occasional hip pain," he explained.

Burton, an assistant professor of surgery at the School of Medicine, said the technique is especially expected to improve hip surgery in elderly patients with arthritis. In this severe kind of degenerative bone disease, reconstructive surgery has not been satisfactory because of a tendency of the older prostheses to deteriorate.

In the old method, some artificial joints were fixed to the bone with screws which became loose with time. In others, the metal also tended to wear out cartilage tissue in the hip socket creating a painful condition for the patient, Burton said.

"For certain hip conditions, the combination of metal and plastic is more satisfactory than the old devices. Metal and plastic get along better with less friction," he added.

-more-

The new cement, which is as strong as bone, has also made a big difference in results, Dr. Burton said. It welds prostheses into place by filling space in and around them, and gives wide surface for weight-bearing, which could not be achieved previously.

The Stanford surgeon reported that 40 patients at Stanford University Hospital and Santa Clara Valley Medical Center received the new artificial hip joints last year under an experimental program approved by the FDA. Under similar programs, this total hip replacement has been carried out at certain medical centers across the country.*

"Before the operation these patients were very much in the disabled grade," he said. "Now the patients are in the excellent to good categories."

Burton said the patients were able to walk out of the hospital on their own strength or with the help of cane or crutch. All patients were free of their original hip pain approximately two weeks after the operation.

Hospital stay for these patients was shortened from an average of six weeks to two and a half weeks, depending on the patient's strength. This is due to the new bone cement which permits full weight-bearing postoperatively.

"In the past, reconstructive hip surgery could require lengthy physical therapy and sometimes as long as a year before the patient could walk," the surgeon said.

The new technique was developed by Dr. John Charnley, a British orthopedic surgeon who has tested it in 4,000 patients. Burton spent a period in England studying the new method and modified it for application to Stanford patients.

---

* One patient to undergo such operation in recent months in Boston was Eugene Ormandy, conductor of the Philadelphia Symphony Orchestra. (Editor).

STANFORD -- Frank H. Roberts of Palo Alto, has been appointed president of the Stanford University Hospital board of directors, Stanford President Richard W. Lyman announced Wednesday, (Nov. 3).

Roberts succeeds Kirk Jeffrey, a former Palo Altan who served on the hospital board since 1968. Jeffrey is now senior vice president of Union Bank in Los Angeles.

An attorney with the law firm of Pillsbury, Madison, and Sutro of San Francisco, Roberts was first appointed to the hospital board in June, 1970. He is a graduate of DePauw University, Greencastle, Indiana, and holds a doctor of law degree from the University of Michigan.

Roberts lives at 1295 Dana Avenue, Palo Alto.

###

STANFORD -- Dr. Norman Shumway, Stanford University's pioneering cardiovascular surgeon, has received the Rene Leriche Prize from the International Society of Surgery.

The prize, considered one of the most distinguished in cardiovascular surgery, pays tribute to valuable work in surgery of the arteries, and clinical and experimental work on diseases of the heart.

Shumway has also developed the techniques used in heart transplantation.

In a letter to Dean Clayton Rich of the School of Medicine, Dr. J. van Geertruyden, secretary general of the society, wrote:

"The Rene Leriche Prize crowns a surgeon considered the most eminent in the domain of cardiovascular surgery."

The prize, awarded every other year by the 3,200-member international society, was first announced at its 24th Congress held earlier this fall in Moscow.

The School of Medicine was notified of the award yesterday (Nov. 2).

STANFORD -- The first linear accelerator to be used in this hemisphere for super voltage radiation therapy is being retired. The machine has been dismantled and removed from the Department of Radiology at Stanford University Medical Center, where it will be stored until it can be moved to the Smithsonian Institute in Washington, D.C.

After treating an estimated 8,000 patients over the last 16 years, Stanford's accelerator will take its place in history at the Smithsonian Institute when arrangements can be made, according to Dr. Henry Kaplan, chairman of the Radiology Department at Stanford University School of Medicine. He said that he wrote to officials at the Smithsonian offering to donate the instrument to them, and they agreed to accept it, but have not yet sent him any authorization or shipping instructions.

The pioneering apparatus, used to destroy tumors by bombarding them with radiation produced from electrons, will probably be displayed in a new hall of nuclear science which the Institute is planning, said Dr. Kaplan. "It's going to have a place of honor among respected company," he added, such as the first cyclotron and the first heavy ion linear accelerator.

The accelerator was designed and built jointly by researchers at the University's Medical School Radiology Department and Microwave Laboratory, with grants from the American Cancer Society and the National Cancer Institute, NIH. It was first installed in 1955 at Stanford's former teaching hospital in San Francisco, and then moved to the Medical Center with the Medical School in 1959.

The device took almost five years to assemble, said Dr. C. J. Karzmark, head of radiologic physics in the Radiology Department. "It was a kind of fallout from high energy physics research and the radar technology of World War II, and a number of physicists, including myself were involved with its development," he explained.

For clinical purposes, electrons injected into a vacuum cylinder called an accelerating wave guide, are accelerated by microwave power to a high velocity and aimed at a specific tumor tissue or used to produce penetrating X rays.

This model was particularly suited for treating cancers of the head and neck, prostate or bladder. The Stanford researchers also developed a specialized technique with this accelerator for treating an inflammatory skin lesion known as mycosis fungoides which can become malignant.

One of the first patients to benefit from the accelerator, Dr. Karzmark recalls, was a two-year-old boy with retinoblastoma, a tumor of the retina in the eyes of young children that can lead to blindness. The young patient had lost the vision in one eye, but his other eye was saved because doctors were able to destroy the tumor with radiation from the accelerator.

-more-

"Such treatment requires the utmost precision," explained Dr. Karzmark. The tiny field of the tumor must be defined and destroyed without damaging the nearby optic nerve and other healthy tissue. "Today, retinoblastomas are treated at Stanford with one of the newer accelerators, but in 1955 there was only one model and because of it, that boy, who is now 17, still has his sight."

The Stanford device was the forerunner of several commercial accelerators first constructed for medical use in the early 1960's, and now numbering well over 100 in this country. The Division of Radiotherapy at Stanford Medical Center has two commercial models, both made by Varian Associates, a California instrument firm whose scientists worked closely with Stanford researchers to improve the medical linear accelerator. Stanford's first apparatus is being replaced by a third modern accelerator, also from Varian, and valued at $200,000.

"The new machine will have a very sharply focused and defined X-ray beam that can be accurately and speedily directed at a tumor without irradiating a large body of surrounding tissue," said Dr. Karzmark. The beam is also more penetrating so 17 tons of shielding is being added to the treatment room. This accelerator is almost one of a kind, he commented, since it has been specially adapted by the company to fit the existing mounting and rotating patient chair of the present room.

Stanford's early device proved invaluable, but it is obsolete now, said Dr. Karzmark. Current generator accelerators have high output and new functional accessories to facilitate more treatment procedures. The first accelerator is history.

STANFORD -- Dr. Henry S. Kaplan, chairman of the Department of Radiology at Stanford University School of Medicine since 1948, will step down from his administrative responsibilities at the close of the current academic year.

In resigning as department chairman, he stressed his desire to relinquish administrative duties and devote himself more fully to teaching and research.

The announcement of Dr. Kaplan's decision was made Wednesday, December 22, by Dean Clayton Rich. Dr. Rich said he plans to appoint a search committee to aid in the selection of a new department chairman.

Dr. Rich characterized Dr. Kaplan as one of the most distinguished members of the medical school faculty, and expressed his appreciation for "tremendous achievements and outstanding contributions to Stanford University."

One of the leading international authorities on cancer, Dr. Kaplan conceived the use of the linear accelerator for medical purposes. After helping design the necessary apparatus, he set standards for its use. He has also pioneered in the development of radiotherapy techniques which have resulted in dramatic gains in the treatment of cancer, especially Hodgkin's Disease and other malignant lymphomas.

Dr. Kaplan has done extensive work over the years on radiation-induced leukemia in mice, and his studies have led to the discovery that such tumors in mice are really caused by a latent virus which is triggered by the radiation exposure. It was for his accomplishments in this area that the Leukemia Society of America selected him to receive the 1971 Robert Roesler deVilliers Award for achievement in leukemia research.

Dr. Kaplan has received international recognition for his work. He was made a Chevalier de la Légion d'Honneur by the Republic of France, and Italy has awarded him its Order of Merit. In 1969, he received the Atoms for Peace Award, the only physician to be so honored.

A 1940 graduate of Rush Medical College of the University of Chicago, he served his internship and residency at Michael Reese Hospital in Chicago. Following further postdoctoral training at the University of Minnesota, he was an assistant professor at Yale and a radiologist at the U.S. Public Health Service before coming to Stanford in 1948.

STANFORD -- Betty Johnson, Stanford University Hospital's third longest surviving heart transplant patient, died late Saturday night (Dec. 18) at the Hospital.

Mrs. Johnson, 47, died from late rejection of her new heart.

A housewife from Logan, Utah, she became the 17th heart transplant patient operated on by Dr. Norman Shumway and his surgical team on September 3, 1969.

Mrs. Johnson is survived by her husband, Homer, an educational consultant, and four children, Jay, 25; Jeff, 21; Jim, 18; and Jarid, 13.

Funeral services will be private.

Fifteen of Stanford's 38 heart transplant recipients are now living.

STANFORD -- Nurses are apparently a fairly straight-laced group, but things may be changing.

At least that's the conclusion which can be drawn from a recent study by a team of Stanford University scientists concerning the use of marijuana by nurses and nursing students.

Few practicing nurses have smoked marijuana, but a significantly higher percentage of nursing students have used the drug, the Stanford researchers found. Results showed that of 1,171 students and 962 nurses surveyed, 13 per cent of the students and 3 per cent of the graduates had smoked marijuana in the past, while 4 per cent of the students and 1 per cent of the nurses classified themselves as current users.

The survey was conducted by Drs. Martin R. Lipp and Samuel G. Benson, residents in psychiatry at Stanford University School of Medicine, and Patricia S. Allen, a graduate of Stanford's School of Nursing and now a staff nurse at San Francisco General Hospital.

The responses were obtained through questionnaires distributed in the spring of 1970 at the conventions of the National Student Nurses' Association (NSNA) and American Nurses' Association (ANA).

"Results indicate that cannabis (marijuana) use, past and present, is significantly more prevalent among student respondents," the authors wrote in their report, published in the December issue of the American Journal of Nursing.

"Exposure to cannabis (being in the room or at an event where marijuana was being used) follows the same pattern. However, there is no significant difference between the two groups with regard to alcohol and cigarette use," they continued.

Responses from the two conventions were analyzed with respect to several variables--age, graduating class, marital status, and state of residence. Single respondents revealed more marijuana use than married respondents, but the most significant differences were related to geography.

-more-

Some states had no marijuana users. In others, particularly on the East and West Coasts, large numbers of students had experience with marijuana. In New York, for example, some 67 per cent of the student respondents had been exposed to cannabis use, and 31 per cent had used the drug in the past.

These results indicate that, in terms of geographic distribution, the nursing sample paralleled marijuana use among medical students.

Lipp, Benson and four other scientists conducted a similar study at four medical schools (also in the spring of 1970), which revealed that past marijuana use ranged from 17 per cent at one midwestern school to about 70 per cent in schools on either coast. In all, half of the 1,063 responding medical students had smoked marijuana and 30 per cent were current users.

The highest marijuana usage rate among nursing students was significantly lower than the highest percentage among medical students, the authors noted in the new report.

Predictions for the future use of the drug by nursing respondents followed the same pattern as the other results. Few practicing nurses said they would try marijuana regardless of possible medical or legal changes. "But, a significant minority of NSNA (student) respondents would expect to use marijuana as either the medical or legal status changed," Lipp, Benson and Miss Allen found.

The discovery that any medical personnel have used, currently use, and foresee continuing to use marijuana in the future is "remarkable," according to the authors, since prospective doctors and nurses using the drug jeopardize not only graduation, but also state licensure and employment.

This use of marijuana by medical personnel in the face of legal hazards raises serious questions, particularly since marijuana is at least partially a medical issue, they said.

"The health professions must soon come to grips with the fact of marijuana use among its own members," they concluded. "If medical authorities cannot convince nursing students to refrain from using marijuana, persuading the population at large seems unlikely."

The study was supported by a grant from the Commonwealth Fund of New York.

HEART TRANSPLANTS/

Patient #38, Transplant #39 12/15/71 - Howard Paul Overson, 32

FOR FURTHER INFORMATION CONTACT: Gary Cavalli 415: 321-5310

STANFORD--Stanford University Hospital surgeons performed a heart transplant operation Wednesday afternoon (Dec. 15) on Paul Overson, 32, from Albuquerque, New Mexico. He is reported to be in satisfactory condition.

Hospital policy has been to withhold names of heart transplant recipients, unless a recipient requests that his name be released. In this case, Overson's relatives revealed his name to Albuquerque newspapers and the Hospital has confirmed it.

Overson has been disabled by his heart condition for the past year. Prior to that he was an insulation worker. He is married and has two children. At 32, he is the youngest of the 38 heart transplant patients to be operated on at Stanford.

Including Overson, 16 of Stanford's 38 heart transplant recipients are now living.

STANFORD -- John Dolly, a part-time Stanford Medical School employee fired for allegedly taking part in a sit-in last April, will get his job back.

Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine, has upheld the recommendation of a grievance committee which urged the rehiring of Dolly.

Dolly was employed by the Department of Genetics. He was one of five University employees fired for allegedly taking part in a sit-in April 9 at Stanford University Hospital. After extensive hearings, two of the five (including Dolly) have been reinstated. The firings of two other employees have been upheld, and the grievance procedure for a fifth employee is pending.

The three-member grievance panel said Dolly's participation in the sit-in was minimal. "His presence was involuntary and his participation was directed primarily by his concern for the physical safety of himself and particularly of his pregnant wife," the committee stated.

The panel recommended Dolly's immediate reinstatement to his previous position, with consideration given to "some remedial compensation."

Dr. Rich ruled that Dolly should receive one-half of back pay equivalent to the amount he would have earned August 9 through October 22. This is the period during which there was a hiatus in the active hearings of Dolly's case in spite of University efforts to expedite the proceedings, he said.

Dr. Rich also ruled there was no basis for Dolly to receive back pay from the date of firing (June 23). He said the University could not be held responsible for Dolly's failure to disclose information that would have cleared him of the charges against him. This was Dolly's choice as a result of which the University did not receive the services he otherwise might have performed.

Dolly has maintained he could not discuss his role in the sit-in because of a pending court case against him stemming from the same incident.

"The University administration acted reasonably in firing Dolly on the basis of facts known to it at the time," the grievance panel wrote. "Dolly voluntarily withheld mitigating information which could not have been obtained without his cooperation.

"The choice to withhold (information) was doubtless a difficult one, but the University cannot be held responsible for the difficulty in which Dolly found himself."

STANFORD -- Dr. John R. Hogness, president of the newly-formed Institute of Medicine in the National Academy of Sciences, will deliver the keynote speech at the dedication of the new $560,000 Psychiatry Clinic Building at Stanford University Medical Center, Thursday, December 9.

The public ceremony marking the official opening of the adult and child clinic facility will begin at 2:30 p.m. in the Dean's Courtyard at the School of Medicine. Dr. Hogness will be introduced by Dr. Clayton Rich, dean of the School of Medicine.

This will be Dr. Hogness' first public statement on mental health since assuming the presidency of the Institute last August.

A 1946 graduate of the University of Chicago School of Medicine, Dr. Hogness served as an administrator and faculty member at the University of Washington for 21 years before accepting his present position.

After six years as medical director of the University Hospital, Dr. Hogness was appointed dean of the School of Medicine and chairman of the Division of Health Sciences in 1964. He became executive vice president of the University in 1969. From 1970-71, he served as chairman of the Board of Health Sciences and director of the Health Sciences Center, composed of six colleges, two hospitals, and four health care and research centers.

Following the dedication ceremonies, an open house will be held for the public in the new building and also at the Department of Psychiatry's inpatient facility at Hoover Pavilion.

The new two-story redwood building was added to give the psychiatric outpatient program at Stanford space it urgently needed and to provide a more pleasant, informal setting for individual and group therapy sessions. Completed in mid-August and now being landscaped, it houses the department library and staff offices, group therapy rooms, and Adult and Child Psychiatry Clinics.

"Between the adult and child clinics, we'll be able to handle close to 20,000 patient visits per year," said Dr. Alan Rosenthal, director of the Child Psychiatry Clinic. "Every staff member has an office, whereas in the past most of our residents had to share offices. Now everyone is free to see many more patients."

Located just south of the main center, the new facility is adjacent to the Edwards Building, which formerly housed overcrowded clinics, department offices and laboratories.

The removal of the clinics and offices from Edwards has freed space for the broad interdisciplinary study of violence and aggression at Stanford, directed by Psychiatry Department chairman Dr. David Hamburg. The balance of the vacated space will be department laboratories for Psychiatry and Biochemistry.

Stanford's psychiatric program employs the "team treatment" concept, in that faculty psychiatrists, social workers, residents and psychologists are all involved in developing therapy for clinic outpatients. The floor plan in the new building facilitates this approach. -more-

"We designed the new clinic floor plan so that teams of doctors are physically located together in clusters of offices," said John Hornback, resident architect at the Medical Center. "Groups of four or five offices are situated around small waiting rooms."

The clustering of offices provides waiting patients with more privacy and reduces the amount of corridor space.

"In the new building we avoid the long walk down a corridor, which sometimes has a 'last mile' feeling for patients," said Dr. Peter Rosenbaum, director of the Adult Psychiatry Clinic.

The building also features a two-story covered courtyard, equipped with sliding panels on two sides for circulation.

The 18,000 square foot structure was designed with economy and flexibility in mind, according to Hornback.

"Outpatient psychiatric therapy doesn't have to take place in a high cost, concrete structure," he said. "With no need for laboratory utilities, we could construct a low cost facility.

"In terms of flexibility, all the interior partitions are non-load bearing and can be easily moved. The carpet and ceiling are continuous, so when a partition is moved, the room still looks finished. Additionally, the building can be taken apart by 30-foot sections and relocated by housemoving methods."

Hornback's staff members Jim Brenner and Ray Rooker carried major responsibility for designing the building, along with Stanford Hospital's Engineering Department. Welch Construction Company of Mountain View was the builder.

Funds to finance the building came from private sources. Plaques will honor the gifts of two major donors--John C. Cosgrove and Mrs. George A. Winzer. The upper floor of the building will be named the Emilie Dohrmann Cosgrove Psychiatric Clinic, in honor of Cosgrove's late wife, who was a member of the class of 1933 and a former trustee of the University. One of the wings on the first floor will be called the Frances Winzer Wing in honor of Mrs. Winzer.

Four members of the Stanford faculty were recently elected to membership in the Institute of Medicine, including Dr. Robert A. Chase, professor and chairman, Department of Surgery; Dr. Hamburg; Dr. Donald Kennedy, professor and chairman, Department of Biological Sciences; and Dr. Joshua Lederberg, professor and chairman, Department of Genetics.

Dr. Hogness' brother, Dr. David Hogness, is a professor of biochemistry at Stanford.

STANFORD -- A new, non-surgical treatment, expected to replace the now common surgery of the prostate, is being investigated by urologists at the Stanford University School of Medicine.

The treatment, still in the experimental state, utilizes a female hormone, medrogestone, given orally or by injection. It shrinks the diseased prostate, making an operation unnnecessary.

The work is directed by Dr. William R. Fair, assistant professor of surgery in the Division of Urology.

Dr. Fair said that benign prostatic hypertrophy or prostate enlargement is a common condition in males over 50. The prostate is a gland in the male situated around the neck and exit of the urinary bladder and through which runs the beginning of the urethra--the passageway for urine.

In one in five males, the prostate enlargement is severe enough to obstruct the urine passageway, resulting in inability to empty the bladder.

The most common treatment for this condition is prostatectomy, a simple but costly surgical procedure for removal of the prostate. Thousands of prostatectomies are performed on males in the United States yearly.

Dr. Fair and his associates believe that medrogestone offers hope of becoming the treatment of choice for this disease in the future, provided that clinical trials demonstrate its effectiveness.

This particular hormone appears to be free of the undesirable side effects associated with female hormone treatment, Dr. Fair said. These included male breast enlargement and temporary loss of sexual potency.

However, before recommending hormone treatment for the prostate on a routine basis, the Stanford urologists want to know if medrogestone actually has any effect on the antibacterial factor found in prostatic and seminal fluids.

"This is important," said Dr. Fair, "because we want to avoid compromising the patient's natural defenses against bacterial infections."

In 1965, Fair working with Dr. Thomas A. Stamey, Stanford professor of surgery, discovered that seminal and prostatic fluids contain a potent antibiotic substance which kills bacteria responsible for urinary tract infections. Their discovery not only accounted for the absence of urinary tract infections in healthy males, but explained how the body fought off bacteria that caused such infections.

"If further study confirms that medrogestone is effective in humans and has no effect on the antibacterial factor in prostatic fluid, prostate surgery for this benign disease may become a thing of the past," Fair said.

In addition, under a $53,105 grant from the National Institutes of Health, Dr. Fair and his associates plan to:

. Study the biochemical nature of the antibacterial factor in prostatic and seminal fluids, and its clinical importance as a defense mechanism against urinary tract infections.

. Investigate the possibility that the periurethral glands of the female (the counterpart of the male prostate in the female) may secrete a similar substance, and that this agent is responsible for the absence of harmful bacteria on the urethra and external vagina of normal females. ### 1/31/72

STANFORD -- The Stanford University Medical Center has appointed Caudill Rowlett Scott of Houston and Los Angeles as executive architects to complete the initial step in forthcoming expansion at the Center. Dr. Clayton Rich, dean of the School of Medicine and vice president for medical affairs, made the announcement today (January 19).

The firm's specific task will be to carry out phase one, step one, in the master plan for the development of the Medical Center, said Dr. Thomas A. Gonda, hospital director.

Dr. Gonda said that this step calls for needed expansion of the Hospital's intensive care unit and clinical laboratories, and relocation of several supportive services.

John Hornback, resident architect at the Medical Center, elaborated on the plans for expansion:

"Basically, we're adding space to accommodate the clinical laboratories and dietary service, including the cafeteria and dining rooms," he said. "This will free space on the first and second floors to relocate and enlarge intensive care, diagnostic radiology, and other patient service and administrative functions."

The most recent master plan for the Medical Center's development, completed in 1970 by Bertrand Goldberg Associates of Chicago, set the basic framework for this expansion. Caudill Rowlett Scott (CRS) will work from this plan, reviewing and revising it to the extent that it is necessary to complete this step.

Dr. Gonda, Dean Rich, and Hornback were part of a 10-member search committee charged with recommending a new architect. In their report to Stanford's Board of Trustees, the committee said:

"It was felt that CRS offered a fresh and innovative approach to programming and planning that had proven itself on a number of recent projects of similar scope. They have received consistently high praise from their former clients. They have exceptional ability to communicate with the client and willingness to respond to his needs and desires in producing the final design."

The committee added that previous studies of design criteria by CRS indicated "a sensitivity to the environment and to aesthetic qualities that will be important to our project."

CRS, a full-service firm of architects, planners and engineers with over 300 employees, has undertaken projects in 40 states and 10 foreign countries since its birth in 1946. The winner of over 100 national awards for innovation in design, the firm last week received the 1972 American Institute of Architects award, given annually to the outstanding architectural firm in the country.

Previously known primarily for design of schools and educational buildings, CRS established a health facilities division in the early 1960's, which now handles almost half of the firm's volume. CRS recently developed the master plans for the medical centers at Tulane and Texas Tech University.

An important and unique feature of the CRS operation is the use of on-site project teams. This technique involves the client/user in making decisions concerning significant design concepts.

The Houston-based firm will work out of its Los Angeles regional office on the Stanford project. CRS is currently engaged in designing the Santa Clara County office building. ### Mailed 1/19/72.

STANFORD -- Dr. Robert A. Chase, professor and chairman of the Department of Surgery, has been named the first Emile Holman Professor of Surgery at Stanford University School of Medicine. The announcement was made today (January 17) by Dean Clayton Rich.

The endowed professorship honors Dr. Holman, professor and executive head of the Department of Surgery at Stanford from 1926 to 1955.

Dr. Chase, a 1945 graduate of the University of New Hampshire, obtained his M.D. from the Yale School of Medicine in 1947. Following surgical internship and residency at New Haven Hospital, he served eight years as a chief surgeon in the U.S. Army. He was a teaching fellow in plastic surgery at the University of Pittsburgh and a surgical faculty member at Yale before being appointed to his present post at Stanford in 1963.

The author of many clinical and research publications, Dr. Chase is chairman of the Graduate Education Committee of the American College of Surgeons. He is also a consultant to the Surgeon-General of the U.S. Air Force.

Dr. Holman, a 1911 graduate of Stanford, was a Rhodes Scholar at Oxford University before obtaining his M.D. from Johns Hopkins University in 1918. He received further training at Harvard Medical School and was a faculty member at Western Reserve University Medical School in Cleveland before coming to Stanford in 1925.

Long considered one of the nation's finest cardiovascular surgeons, he contributed to the development of the surgical treatment of "blue babies" and was the first to perform the delicate operation on the West Coast.

In 1952, Dr. Holman received the Rudolph Matas Award in Vascular Surgery, generally regarded as the world's highest recognition for surgery of the heart and blood vessels. The winner of numerous other awards and honors, he has authored three books, contributed to four others, and published 187 articles in medical journals.

-more-

Dr. Robert A. Chase/Holman Professor of Surgery

222

The endowed professorship was made possible by a bequest from the estate of Deane and Louise Dart Mitchell.

Louise Dart, a native of Rock Island, Illinois, studied Latin at Stanford for two years before marrying Deane Prescott Mitchell in 1897. Mitchell, a classmate and close friend of Herbert Hoover, received his A.B. in geology at Stanford in 1896.

Mitchell was an expert in the mining and processing of ores. His successful mining career took him and his wife on extensive trips all over the world for over 50 years. They retired to Bermuda in 1949, where Mitchell died in 1965 at the age of 91.

Despite failing health, Mrs. Mitchell continued travelling after her husband's death. She died in Santa Barbara in 1970 at the age of 93.

The Mitchells maintained close ties with Stanford throughout their lifetime and agreed to make the University their chief beneficiary. In her last years Mrs. Mitchell decided to use the bequest to establish an endowed professorship in the name of Dr. Holman, their lifelong friend.

STANFORD -- Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology, has been named the first holder of the Maureen Lyles D'Ambrogio Professorship at Stanford University School of Medicine, Dean Clayton Rich announced today (January 12).

The endowed professorship was made possible when Stanford received a gift of approximately 100 acres of land on the Monterey Peninsula from N.J. D'Ambrogio of Berkeley (formerly of Carmel) in April of 1970. At that time, the Maureen Lyles D'Amborgio Memorial Fund was created in honor of D'Ambrogio's daughter, Maureen, who died of cancer in Berkeley on March 8, 1967.

The Fund will be used to maintain the professorship, which will always be held by a faculty member engaged in cancer research.

Dr. Kaplan, chairman of the Department of Radiology since 1948, recently announced he will step down from his administrative responsibilities at the close of the current academic year to more fully devote himself to teaching and research.

One of the leading international authorities on cancer, Dr. Kaplan conceived the use of the linear accelerator for medical purposes, and helped design the necessary apparatus. He has also pioneered in the development of radiotherapy techniques which have resulted in dramatic gains in the treatment of cancer, especially Hodgkin's Disease and other malignant lymphomas.

Last year Dr. Kaplan received the Robert Roesler deVilliers Award for achievement in leukemia research from the Leukemia Society of America. In addition to awards from France and Italy, he won the Atoms for Peace Award in 1969, the only physician to be so honored.

A 1940 graduate of Rush Medical College of the University of Chicago, he served his internship and residency at Michael Reese Hospital in Chicago. He went on to the University of Minnesota and Yale before coming to Stanford in 1948.

D'Ambrogio is a Stanford alumnus of the class of 1917. Following his graduation and a brief academic career, he entered the field of financial consulting and became an authority on sugar production and consumption.

The property donated to Stanford, known as Kent Manor, overlooks the Pacific Ocean on Highway 1, about three miles south of Carmel.

Heart Transplant #40, Patient #39

STANFORD -- Stanford University Hospital surgeons performed a heart transplant operation Friday morning (January 7) on James Casper, 32, of Canton, Illinois. He is reported to be in satisfactory condition.

The operation was performed by a team headed by Dr. Norman Shumway.

Casper, a welder at International Harvester Co. for eight years, has been disabled by his heart condition since last August. He is married and has two children.

Including Casper, 14 of the 39 heart transplant patients operated on at Stanford are now living.

Hospital policy has been to withhold names of heart transplant patients if they so request. In this case, Casper's family released his name to his home town newspaper.

STANFORD -- Donald Wanjon, the 33rd heart transplant recipient operated on at Stanford University Hospital, died yesterday afternoon (January 5). Doctors at the Hospital said Wanjon died from pneumonia.

Wanjon, 47, was a retired schoolteacher from Rochester, N.Y. He received his new heart on August 10, 1971. He is survived by his wife, Norma, of Rochester, and three children: Mark, 23, of Albuquerque, New Mexico; Christopher, 18, and Rebecca, 12, both of Rochester.

Another Stanford heart transplant recipient, Herbert Juster of South Braintree, Massachusetts, died Sunday morning at Massachusetts General Hospital. Doctors at the Hospital listed pneumonia as the cause of death.

Juster, 48, received his transplanted heart on April 24, 1971. He is survived by his wife, Rose.

Thirteen of the 38 heart transplant patients operated on at Stanford are now living.

STANFORD -- Stanford University Hospital has reorganized selected in-patient care units so the nurse can return to bedside care.

Instead of one registered nurse responsible for each patient unit, there are two people responsible for a unit. An R.N. is in charge of the clinical activities, or nursing care, while a lay manager handles clerical and other non-clinical functions.

After a year of preliminary study, Nursing Services has implemented a pilot program of restructured care delivery and administration on two patient units. The project, begun October 4, will be evaluated next spring and then gradually phased into all other in-patient units at the Hospital.

"Nurses are trained to care for patients, but they are often overloaded with paper work," said Sue Brueckner, director of the nursing demonstration project. "In the new organization, non-nursing personnel are responsible for all non-clinical duties on the patient unit so the nurses are free to concentrate on patient care."

Clinical activities include all aspects of patient care and any administrative tasks that require nursing judgment, such as evaluating new equipment, assigning nursing personnel to patients, and communicating with others about patient care, according to Miss Brueckner. Non-clinical activities are any other administrative or clerical duties necessary for the functioning of the patient care unit.

Titles of some personnel have been changed to be more inclusive of their duties and new roles have been developed. The clinical nursing coordinator is responsible for the overall delivery of nursing care on the unit. She supervises team leaders and other nurses who care for the patient. All other activities are directed by a unit operations manager working with unit secretaries.

The unit operations manager has taken over the administrative detail, such as budget and supplies, maintenance and repairs and interdepartmental communications, previously handled by the nurses. Now, one person--the clinical nursing coordinator--can manage all the clinical activities in a unit because she no longer has any administrative duties. Communication between the unit leader and nurses on her unit is direct, since a cumbersome hierarchy of associates and assistants has been eliminated.

-more-

"The nurses are very enthusiastic about the changes, and appreciate the total nursing responsibility," said Miss Brueckner. "We think that the quality of care will also improve," she continued, "because now nurses are doing just what they have been trained to do. They can do a better job when they enjoy what they are doing and are not distracted by non-clinical clerical work."

Patient unit organization was revised after a year of study and evaluation by a nursing project committee that included representatives from all levels of nursing. Committee members worked with Miss Brueckner and administrative aid Steve Tani to review the literature, observe what other institutions were doing, identify the roles of personnel and assess the strengths of the traditional system at Stanford University Hospital.

The organizational plan developed is a combination of many ideas from various hospitals and much brainstorming. "No individual part is particularly original, but the entire package Stanford has put together is unique," said Miss Brueckner. "We have redefined and separated clinical and non-clinical roles in a novel and exciting program," she commented.

Clinical nursing coordinators in the two demonstration units are Joan Fair, who was formerly an inservice instructor in the coronary care unit, and Joan Mersch, who came to Stanford from the University of Colorado. Dick Pettingill is the unit operations manager for the two units. Each patient unit will have its own clinical nursing coordinator, but a unit manager will cover three to four units.

Miss Brueckner says that Nursing Services will be ready to implement the program in additional patient units this spring. She anticipates that by 1975, all 31 of the Hospital's in-patient care units will be operating under the restructured program of nursing care and administration.

EDITORS: The Fourth National Conference on Methadone Treatment will be held at the Sheraton-Palace Hotel in San Francisco from Saturday, January 8, through Monday, January 10. The conference will consist primarily of workshops and study sessions for participants with professional involvement in methadone treatment of narcotic addiction.

Chairman for the conference is Dr. Avram Goldstein, professor of pharmacology at Stanford University School of Medicine.

California State Assemblyman John Vasconcellos will deliver the opening speech at 9:00 a.m., Saturday (January 8). Dr. Jerome H. Jaffe, Director of the Special Action Office for Drug Abuse Prevention, Executive Office of the President, Washington, D.C., will give the concluding speech at 11:00 a.m., Monday (January 10).

All speeches and study sessions at the conference will be open to newsmen. However, the physical arrangements at the conference do not permit television coverage. For the benefit of television stations that wish to attend, the participants in the conference will be available for interviews.

In addition, a press conference (open to all the media) will be held in the Regency Room of the Sheraton-Palace at the conclusion of the conference, 12:30 p.m. on Monday (January 10). Participating in the press conference will be: Dr. Vincent P. Dole of the Rockefeller University of New York, a pioneer in developing methadone treatment; Dr. Robert L. DuPont, director of the Narcotics Treatment Administration in Washington, D.C.; Dr. Goldstein, and Dr. Jaffe. They will report conclusions reached at the conference and answer questions from the press.

The conference is being sponsored by the National Association for Prevention of Addiction to Narcotics (NAPAN) and the National Institute of Mental Health (NIMH).

Under Goldstein's direction, an Addiction Research Laboratory is currently being developed at Stanford to continue and expand research into the most important problems of narcotic addiction.

STANFORD -- The traditional short cap worn by men in the operating room was not designed with today's hirsute male in mind. So at Stanford University Hospital, operating room personnel can choose among several styles of head coverings and masks according to the length and distribution of their hair.

Since evidence indicates that fallout from hair is a potential source of contamination in the operating room environment, long hair, beards, moustaches and sideburns must be covered.

"Surgical infection is the fourth leading cause of death in this country," said Mrs. Ludmila Davis, director of the Hospital's operating and emergency rooms. "Here at Stanford where we do 11 to 1200 operations a month, we cannot afford to be complacent about exposed hair."

Hair is a natural breeding ground for some bacteria, and the more unrestrained it is, the greater the hazard for both the patient and the doctor, according to Mrs. Davis. A beard not effectively covered, for example, could contaminate a patient and also pick up other germs in the environment which might then infect the bearded owner or those around him, she explained.

"In defense of everyone, then, we've had to design more inclusive head and face cover for those in our operating rooms keeping up with the contemporary long hair fashions," Mrs. Davis said.

She has created two new styles of protective headgear which the American Hospital Supply now manufactures to sell to other hospitals. One version, the "Lawrence of Arabia Helmet," is made to cover long hair, sideburns and a beard. Another design, the "Stanford Helmet," or "Davis Hat," takes care of sideburns and longish hair, and can be worn with a beard cover attached to either side near the ears. Both are made of light weight, disposable cloth that provides comfortable ventilation and eliminates laundering.

Men with moderately short hair sometimes elect to wear the style hat that is worn by many female personnel. However, these hats are made of extremely thin paper that can be easily pierced by stiff bristly hair and whiskers. A few men still wear the original cap, although it is practically useless in most instances, and not available in the operating room, Mrs. Davis said.

With all of the styles, there are improvisations. Males who need their ears free for glasses or stethoscopes, push their caps behind their ears or cut holes in the paper caps. Those who find the extra cloth about their heads and faces uncomfortable or stuffy, wear shorter hats and put tape over their sideburns. One resident who sports a full beard wears an extra wide mask that his wife sews for him.

Not to be out-fashioned by the men in the operating room, the women have begun varying their headdress. Some of the nurses have bouffant hats in subdued colors and others wear a turban style covering.

As long as the possibility of contamination from hair exists, the operating rooms will never relax their standards on covering hair, Mrs. Davis emphasized. ###

STANFORD -- "A lot of people won't understand why I don't want to be a heart surgeon making $200,000 a year in Beverly Hills."

So says David Sachs, M.D. In mid-1969, after over 400 operations, Sachs found himself "looking for a way out of the practice of medicine." He turned from heart surgery to a new career--acting. Today, with three movies and several television dramas behind him, and the prospect of a nationwide series ahead, he feels it was the right move.

"I'm happier than I've ever been before," says The Stanford Medical School alumnus. "I feel like I've just been reborn. It's a total rebirth for me, an awakening of an awareness that was there all along."

For Sachs, the "rebirth" began with a phone call to a friend in the movie industry. Soon he had a walk-on role as a hippie in "Hells Angels--'69" and another small part as a patient in the daytime television show "General Hospital." Hired as a technical adviser for the highly successful movie, "M.A.S.H.," Sachs was taken for a member of the cast by director Robert Altman and wound up playing a surgeon. He followed that up with a role as a Mexican sheriff in "The Road to Salina" with Rita Hayworth.

Sachs' television credits include an appearance on "Mission: Impossible" as a drunken Central American revolutionary, and several roles as doctors and surgeons ("you might call it typecasting") on "The New Interns," "Medical Center," and "The Bold Ones." He's also appeared in pilot films for two series, numerous talk shows, and a recent American Broadcasting Company Movie of the Week ("Earth II").

Medicine for Sachs has now become something of a hobby. He closed his Beverly Hills office a year and a half ago, but remains active as an assistant clinical professor of surgery (heart and lung) at UCLA School of Medicine. During the past 18 months, he has assisted in over 200 surgeries ("just to keep by fingers nimble").

Sachs' original decision to leave the day-to-day surgical routine and go into acting, he claims, was more a matter of seeking escape from the "business" of medicine than of being hit by the acting bug.

"I didn't get a 'bug' really," he says. "I was looking for a way out of the practice of medicine, and I wanted to get into a field where I could be fulfilled.

"I genuinely love heart surgery. What I always wanted to do was practice heart surgery as a hobby--because I wanted to do it, not because I had to do it. I just don't like the business of surgery, the business of medicine, and the all-consuming restrictions it had on my creative being. Things become grating on your soul...sending out bills, the voluminous time spent on forms, phone calls in the night. I found I had to be involved in more than just surgery." -more-

To those who might criticize the notion of an eminently qualified heart surgeon forsaking his practice for the glamor, hot lights, and publicity-oriented world of motion pictures, Sachs has this to say: "To 'just be' a family physician and not specialize 20 years ago was considered ludicrous, a waste of talent. Now that's the word I get today--that it's a waste of talent for me to not be practicing heart surgery.

"The key thing is that I feel I have talent which supersedes heart surgery. Acting is a vehicle, not an end in itself, for me. I don't know where it's leading. But I know I didn't want to be a slave to the practice of medicine. Acting is the vehicle which allows me to explore the many other areas which are open to a creative, innovative human being."

Sachs, a young-looking 40, resembles a Hollywood movie physician more closely than the stereotype of a "real life" doctor. Confident and articulate, his philosophy is to live life to the fullest, without being stifled by any set routine. His hair is voguishly shaggy, his dress "hip" and casual. He drives a new Mercedes-Benz with license plates reading "Sachsy."

"Life," he says thoughtfully, "is similar to a piece of sculpture. Add a little clay, or pull some off, and it completely changes the overall effect. It's the same thing with a person's life. You make a little change, and it can turn his life around.

"I think our society has gone askew in some respects. It makes unfair demands on a young adult by making him choose a career too early in life. I'm not saying there shouldn't be goals, but the concept that a career is all important, this rigidity of the career system, is not, I think, compatible with the needs of our growing people today.

"Flexibility is essential. Not to be flexible--to be rigid in medical diagnosis, in the political arena, and in choosing careers--is a sin."

For Sachs, flexibility has come only recently, since his break from medical practice. Prior to that, his life had pretty much followed the typical pattern of the successful heart surgeon.

Born in New York, the son of Russian immigrant parents, he knew he wanted to become a doctor by the time his family moved out to Southern California some 25 years ago.

"Certain things impress you to go to medical school," he says. "You drive to get the A's, you receive all the adulation. There is no group in the world that needs love more than doctors. They even surpass actors. I know one of the reasons I wanted to be a heart surgeon was because it was one of the most enviable scenes around.

"I wanted to please my parents. I wanted to please everybody. No one was forcing me...I wanted to do it. Now I've finally gotten around to pleasing myself."

After attending North Hollywood High School, Sachs entered Stanford in 1948 and graduated with distinction four years later. During his undergraduate years he was a founder and the first president of Stanford's pre-med fraternity, Phi Rho Sigma. He received his M.D. from Stanford in 1955, and interned there the following year.

Following two years as a flight surgeon in the Air Force, Sachs served six years of residency in vascular and thoracic surgery at UCLA and Johns Hopkins University. In 1964, he became assistant chief of surgery at Los Angeles Veterans Administration Hospital and opened an office in the San Fernando Valley. Two years later he moved his office to Beverly Hills.

The break from medical practice began in 1968, when Sachs, looking for a way out, applied to become an astronaut.

"I wanted to be the first heart surgeon in space," he says. "I wanted to make it...it was a good way out. But I wasn't accepted."

Acting, of course, was another way out.

-more-

"Through all this, I felt I had the aesthetic feeling of the artist," he says. "Finally, I decided to try and involve myself in entertainment. I was on 'To Tell the Truth' about a year and a half ago. I was the only guy they believed could be a surgeon, an actor, and an astronaut. I was the only one crazy enough."

In the beginning Sachs, the heart surgeon, had some doubts about whether Sachs, the actor, would make it.

"When I made my breakaway, I knew I had to do it, but I really didn't know what would happen," he says. "When you reach med school it's all pre-ordained from there...internship, residency, practice. You make it--you get the grades and the degree--or you don't. But to go after something you feel you must do to be a total human being is even more difficult than reaching the status of a heart surgeon."

Along with the actor and the heart surgeon, there are many other sides to David Sachs. Incessantly active, aggressive and hard driving, he pursues everything, as he says, "with total commitment." It is almost as if he is afraid of being called merely "good" and not "great" at all he undertakes.

"I've been successful at everything I've ever done," he says quietly. "That's what's a little frightening to me. I know that sounds a little egomaniacal. But I feel an obligation to be totally committed in everything I do. I've not undertaken many things I wanted to do only because I didn't think I'd do well."

The walls of Sachs' Beverly Hills home are lined with several very professional paintings he has done. At present he is putting the finishing touches on a fascinating "Anatomy Coloring Book" for children. The book will contain drawings of parts of the body with a brief text (written in rhyme) as to the function and importance of that part, plus how to keep it in good shape. The coloring book is just one of the ways Sachs hopes to utilize entertainment in the mass media for public health education.

"I became tired and anxious about having to fix the ravages of time, aging, and disease on the human arterial system," he says. "The answers to better health must come from a strenuous effort through all the media, using entertainment as a framework to disseminate the concepts of better physical and mental health. Education in health is the key--without all the technological crap."

The chief vehicle in this effort may be a nationwide television series on health, starring Sachs. At present, the show is still on the drawing board, but "the prospects look very good," he says. "We're shooting for next fall."

Sachs' own education didn't end when he completed his residency. He received his Master's Degree in Health Education at UCLA last September, and has been accepted for his doctorate in "Health Entertainment, Communication." He was recently appointed consultant and adviser to the Board of Health Education for the State of California.

The next horizon for Sachs may be politics. A member of the government affairs committee of the Beverly Hills Chamber of Commerce for the past several years, he admits half-humorously, as if he is still toying with the idea, "Yes, I'm interested in going into politics."

A much-in-demand speaker, he averages about 200 hours of lectures per year to students and medical groups. "I was guest lecturer at the UCLA Experimental College a while back and spoke on 'Why Not Change Careers?'" he laughs. "Several of my topics are 'Happiness is....' I try to emphasize that, for most people, happiness is doing what you feel you have to do, without being strangled by convention."

His own speeches on happiness, perhaps, provide the best insight into David Sachs. Then again, the answer may lie deeper.

"The key word for me is uniqueness," he says. "I have to be doing the special thing that is only me and that only I can do."

Sachs may be still trying to find that "special thing." Even if he never does, it will make for an interesting search.

STANFORD -- A new system of lifelong education, recycling if you will, of physicians in practice has been devised by the Stanford University School of Medicine.

The pilot effort contains these unique features:

. It is decentralized and uses, to a great extent, community hospitals as centers of teaching.

. Student-doctors do not simply attend lectures, but they enhance their learning by teaching others.

. Courses for doctors in practice are determined by local education needs, as perceived by the doctors themselves and established by audit of hospital patient records.

. Teaching effectiveness will be evaluated by the improvements it makes in patient care. This will be done by audit of patient records before and after doctors have taken a course.

The new approach to continuing education of doctors was developed by Dr. Edward Rubenstein, a practicing physician in San Mateo and clinical professor of medicine.

Dr. Rubenstein said the traditional approach of keeping doctors informed about the latest advances in medicine hasn't worked optimally.

"Merely organizing a catalog of symposia, courses, and lectures is insufficient," he said. "The effect of such programs on the level of actual medical practice is inconclusive. New efforts, adventuresome and experimental, are needed."

The California Medical Association's committee on continuing medical education has encouraged medical schools in the state to increase their activities in the field of lifelong education for doctors in practice.

"There is also strong evidence," Dr. Rubenstein said, "that many physicians are genuinely concerned that they maintain their competence, and are highly motivated to participate in well-conceived programs of postgraduate medical education.

"Furthermore, the public has let it be known that it expects its physicians to keep up to date."

Dr. Rubenstein said Stanford has formed an informal federation of hospitals within Area III of the California Regional Medical Programs (RMP). Area III includes 11 counties, and embraces Stanford's educational responsibility under the state-wide RMP network.

The federation includes Mary's Help Hospital in Daly City, Mills Memorial Hospital in San Mateo, and the Community Hospital of the Monterey Peninsula in Carmel. There are plans to add two other hospitals to the federation in the near future, one probably in the San Joaquin Valley.

Hospitals in this federation have committees on continuing medical education which keep in touch with Stanford. They determine what they need, and Stanford provides faculty to give lectures, hold conferences, consult and take part in other administrative and educational activities of each hospital.

-more-

In addition, each hospital sends 15 staff members to Stanford for two one-week courses during the year. One course deals with the latest concepts of intensive care, the other is a review of basic science and molecular biology.

Each hospital also sends a physician to Stanford for two or more weeks as a clinical fellow to work in a department of his choice where he has an opportunity to refresh his knowledge. He then can take the new knowledge back to his community.

"An adventuresome project, now in its second year at Mills Memorial Hospital in San Mateo, is looking into the feasibility of offering the medical school basic curriculum, as presently taught, to doctors in their community hospitals," Dr. Rubenstein said.

This Back-to-Medical School program makes it possible for doctors who have been in practice for 20 to 40 years to re-enter medical school and "graduate" a second time.

The program is organized into two parts, one dealing with courses in basic medical science, and the other dealing with clinical subjects.

There are now 60 doctors participating in a review of human anatomy. Already completed has been a course in biochemistry extending over a period of 40 weeks. The applied clinical courses given so far have dealt with intensive care, clinical genetics, neonatal emergencies, immunology, allergy, and contemporary urology.

Each speaker, which includes alternately a faculty member or a community hospital physician, provides Stanford's Office of Postgraduate Medical Education a list of the major topics he emphasized in his discussion. This list is reduced to those items which reflect clinical management which can be evaluated by auditing hospital records. Those records completed prior to the course will be used as controls to attempt to evaluate the effectiveness of the course.

"As currently planned, the Back-to-Medical School project will continue for four to five years, during which there will be continuing evaluation," Dr. Rubenstein said.

Stanford also puts on annually a comprehensive review of basic medical science to meet the needs of doctors who want to expand their knowledge of molecular biology.

The first such course will be given at Stanford February 28 through March 3. Teachers will include four Nobel laureates--Drs. Arthur Kornberg, Robert Hofstadter, Joshua Lederberg, and Linus Pauling.

Stanford is planning several other programs for physicians who work in rural communities, Dr. Rubenstein said. There is an indication that for rural areas direct clinical services will prove to be a better educational method than lectures, courses, and symposia.

"We are currently studying the possibility of sending faculty members, especially those in the surgical fields, to work closely with practitioners in rural areas, assisting them with special care problems in their community," he said.

Stanford's program is essentially self-sustaining, Dr. Rubenstein said. The major revenue comes from annual fees paid by the participants. A federal grant, however, will be sought in the future to cover costs associated with the evaluation of the program.

CORRECTION: EDITORS

STANFORD -- Monday (February 14), a news story emanated from the Stanford Medical Center News Bureau concerning use for the first time in the U.S. of human cells as a culture medium for vaccine production. The story incorrectly stated that Pfizer, Inc., a pharmaceutical manufacturer, had been issued a license by the Division of Biologics Standards (DBS) to make the first oral polio vaccine using human cells. The license, according to DBS, has not yet been issued. Pfizer has applied for permission to produce the vaccine and hopes some time this spring or early summer to begin marketing it through normal channels.

DBS, however, has approved human cells for vaccine production in the United States, and standards for their use were published in the federal register last November. A drug manufacturer has to meet these standards before a license is issued. Pfizer, Inc. is in the process of doing this now.

STANFORD -- Human cells stored and grown in a laboratory of the Stanford University Medical Center will be used for the first time in the United States to make the vaccines that protect people against disease.

An oral polio vaccine has been licensed by the Division of Biologics Standards of the National Institutes of Health. It will be produced by Pfizer Laboratories and made available to doctors, hospitals and clinics this spring.

In development by other companies for use in this country are human-cell vaccines for rubella, measles and rabies. All vaccines for human use can be made using human cells as the virus growth medium.

Use of human, rather than animal cells to make vaccines, signals a new era in the practice of vaccination in this country, said Dr. Leonard Hayflick, professor of medical microbiology at Stanford University School of Medicine. He pioneered in the development of a human cell strain during the late 1950's and early 1960's when he worked at the Wistar Institute in Philadelphia.

These cells, developed by Hayflick, will be used as a growth medium for the production of the oral polio vaccine.

Hayflick said use of these laboratory grown human cells would mean:

- Cheaper vaccine production.
- Standardization and unmatched safety.
- Development of vaccines where none previously were possible.
- An end to the senseless slaughter of monkeys whose cells are now widely used to make vaccines.

Present methods for obtaining animal cells are time consuming and costly. To harvest viruses for manufacture of vaccines, living animal cells are used as the "soil," so to speak, on which the viruses grow. Cells of monkeys and chicken embryos are now widely used. Vaccine makers must import thousands of monkeys annually, quarantine them and then kill them.

But in recent years scientists have discovered that cells of monkeys and other animals are often contaminated with other viruses, some previously unknown. They often crop up in the cell cultures, which then must be thrown away.

Also, cells differ from animal to animal, and this makes it difficult to develop a uniform vaccine-growing medium. As a result, the safety of the animal cells cannot be tested for unwanted viruses with absolute certainty.

-more-

The discovery early in 1960 that a virus (SV-40), known to cause cancer in animals, existed in monkey kidney cells used in producing the first lots of Salk and Sabin polio vaccine caused some uneasy moments among federal regulators and vaccine makers alike.

In 1962, Hayflick produced a healthy tissue from cells taken from the lung of a human fetus imported from Sweden, which had liberal abortion laws. Since then, the tissue which he named WI-38, has been used in Great Britain, France, Yugoslavia and the Soviet Union to make vaccines against polio, measles, mumps, and German measles.

The WI-38 cells carry none of the viruses found in monkeys, Hayflick said. Researchers around the world have subjected these cells to the closest scrutiny for undesirable properties, but they have come up only with favorable results.

Cultures of WI-38 cells are stored at the Stanford University Medical Center, which supplies them to laboratories all over the world, including the Soviet Union. The cells are frozen in liquid nitrogen, from which they are thawed for vaccine production.

Hayflick discovered that these normal human embryo cells will divide up to a limit of 50 doublings when grown in culture. A few such divisions, however, increase the number of cells astronomically--for example, 10 doublings will produce 1,024 bottles of cells. At this rate, Hayflick estimates that WI-38 cells stored at Stanford will be able to supply the world's human cell vaccine needs for the next 20 years.

In the U.S., however, commercial use of WI-38 cells for vaccine manufacture was effectively blocked for 10 years by the Division of Biologics Standards (DBS), responsible for licensing all biological products, including vaccines.

Hayflick, who led the battle against the cumbersome and highly risky use of animal cells, blames the delay on excessive skepticism and bias on the part of DBS, in an interview in the winter issue of Stanford M.D., the magazine of the Stanford Medical Alumni Association.

Although by 1964, according to Hayflick, all major scientific questions concerning human cells had been resolved and the cells were regarded safe, officials continued to express "reservations" and "theoretical" objections.

Even before this, Wistar investigators had produced a number of experimental vaccines, and Hayflick had immunized each of his five children against polio with an oral vaccine made in human cells.

An adenovirus (common cold-like) vaccine produced in WI-38 cells was submitted to DBS for licensing in 1965. "No license was issued," Hayflick said, "and the agency used various tactics to stall a decision." DBS's objections continued, the Stanford microbiologist said, even though an identical adenovirus vaccine, made in human cells, had been freely and effectively administered in the United States to a million military recruits not within the authority of DBS.

Meanwhile, in 1968, seven West German laboratory workers died of "green monkey fever" and virologists warned that with the present production methods, "we are sitting on a volcano." The scientists were almost unanimous in recommending a shift from animal cell cultures for growing viruses to human cells. (At this writing, 23 laboratory workers are known to have died as a result of handling monkeys and their cultured cells.)

Back to Washington, DBS soon indicated that it would favor an oral polio vaccine produced in human cells. If there were in fact any deleterious effects from the use of human cells, as some had maintained, there would presumably be less risk from a product that was merely swallowed than from one that was injected.

With the ban now over, Hayflick welcomes the knowledge that will enable human cells to be used for making safer vaccines. But his personal experience has made him less confident about the ability of federal agencies to deal with the complexities of research and development and consumer protection.

It is anomalous, he said, that federal support, on the one hand has mounted a vast research effort to understand disease, while at the same time regulatory agencies are saying that methods or drugs cannot be developed to prevent it or treat it.

STANFORD -- An affiliation for joint teaching of Stanford University medical students has been agreed upon by Stanford's School of Medicine and the Santa Clara Valley Medical Center (SCVMC), the county hospital.

Formal approval was given Tuesday morning (February 1) by the county Board of Supervisors, following prior approval by Stanford.

Stanford and Valley Medical Center have been informally associated for teaching purposes for the past nine years. This new agreement will bring more Stanford medical students to the center for first-hand instruction from hospital staff and Stanford faculty members.

At present, SCVMC has 17 Stanford undergraduates in medicine working in various departments at the hospital, said Dr. Norman Nelson, county director of medical institutions. These students serve as clinical clerks, preparing medical histories and performing patient physicals. Their work is reviewed by the medical staff.

In addition, many interns and residents from Stanford receive advanced clinical training at SCVMC.

Dr. Clayton Rich, dean of the School of Medicine and vice president for medical affairs, said: "The more formal affiliation is to us a most appropriate step forward and will enable Stanford to strengthen its program of medical student teaching in the area of primary care of sick and injured persons.

"In return, we believe that the presence of more Stanford medical personnel at all levels will be of value to the Santa Clara Valley Medical Center," Dr. Rich continued. "This affiliation, then, is one which we believe will be of mutual benefit to the two institutions and will improve the health of people in the area now and in the future."

Dr. Nelson commented: "This is formal acknowledgement of nine years of a gradually developing association based on mutual benefit for Stanford and SCVMC. The advantage to our medical center is in bringing in the expertise of the Stanford medical faculty to the patient care area at the center. This will assure a higher quality of medical care.

"The advantage to Stanford is in the tremendous variety of acute illnesses to which undergraduate medical students and graduate students in specialty training will be exposed."

Stanford faculty members with clinical responsibilities at SCVMC comprise about one-third of the center staff, Dr. Nelson added. He also noted that most of the SCVMC staff has teaching appointments at Stanford.

(ADVANCE) FOR AM RELEASE THURSDAY, FEBRUARY 3, 1972

SAN FRANCISCO -- A Berkeley environmental group and a Stanford University graduate student in genetics are suing the federal government to get the Food and Drug Administration (FDA) to release information on food preservatives the agency claims constitute "commercial property."

In a suit, scheduled to be started Thursday (Feb. 3) in U.S. District Court, the Environmental Defense Fund (EDF) of Berkeley, and Dale B. Hattis of Palo Alto, a doctoral candidate in the Stanford Department of Genetics, will challenge an FDA policy which restricts public access to toxicological data submitted by manufacturers in petitions for food additive tolerances.

Named defendants in the suit are Elliot Richardson, secretary of the Department of Health, Education and Welfare, and Charles Edwards, FDA commissioner in Washington, D.C.

Hattis and EDF said they requested the scientific data because certain food preservatives have recently come under heavy suspicion of producing mutations and cancer. His research deals with genetic mutations.

The pleading sets up that on December 8, 1971, the FDA "refused to give plaintiffs access to requested information on the ground that such information was 'confidential' as that term is used in the Freedom of Information Act."

The suit states that such refusal violates the Act, and asks the court to order the FDA "to give plaintiffs the requested toxicological information."

If the plaintiffs, and the scientific community at large, are barred from information of critical importance in assessing a potential threat to health, the suit contends, the public will be unable to judge whether the FDA is protecting its interests.

Stanford's Nobel prize winning geneticist, Dr. Joshua Lederberg, has submitted a statement on behalf of Hattis, asking for expeditious hearing of the case. Lederberg argues that long court delays in efforts to obtain information about public safety have often had "a chilling effect on this kind of debate."

Lederberg also wrote: "The evaluation of environmental chemicals must be exposed for continuous review by interested scientists.

"Safety evaluation, even if performed to the satisfaction of a regulatory agency, must not be protected as the private property of a sponsor of a new chemical."

Hattis, who once worked for consumer advocate Ralph Nader, has campaigned against the use of lead arsenate in pesticides in the Bay Area.

-more-

Hattis/Food Additive Sodium Nitrite
222

Since July, 1970, Hattis has been trying to gain access to data on the safety of food additives and pesticide residues from the FDA. He has especially sought information about sodium nitrite, used as a color fixative and preservative in almost all salami, hot dogs, and cold cuts.

Hattis said there is concern voiced in scientific journals that sodium nitrite may combine with other food elements to form carcinogenic and mutagenic secondary products called nitrosamines.

He asked the FDA for petitions from the Morton Salt Co. and Tuna Products Corp. about tolerance levels for sodium nitrite. Those petitions, Hattis believes, probably contain most of the scientific information used by the FDA in establishing a tolerance level. He also asked the FDA for all other unpublished information relating to the safety of sodium nitrite.

Hattis said he never received a reply from the FDA until June 1971, when he was told he would have to pay for copying and compiling certain published reports which did not include all the pertinent data.

Since then he was joined in his efforts by EDF, a non-profit corporation with a staff of lawyers and scientists dedicated to preserving the environment. Together, on November 2, 1971, they sent a letter to the FDA requesting the pertinent information in its files.

On December 8, Sam D. Fine, FDA associate commissioner for compliance, wrote back: "Toxicological and other technical information is valuable commercial property that is regarded as confidential information.

"Since the data from the food additive petitions which you have requested is (sic) clearly exempt from disclosure under...guidelines, set by law, we cannot furnish it."

Hattis commented "the real issue is much broader than the questions concerning the scientific adequacy of the data...although the resistence the FDA is putting up increases my suspicion that they have reason not to be very proud of some of it."

The issue, Hattis contends, "is the ability of many parts of the executive branch to stifle informed public review of their policies by obstructing public access to the information on which these policies are based."

Hattis said troubling experimental evidence has come to light after most of the FDA approvals of sodium nitrite additives in various foods. "Without prejudging the adequacy of the FDA's tests, it is also possible that they were insufficiently exacting," he said.

"Time after time when consumers try to find out if the policies of government and industry are beneficial or harmful to the public interest, their access to information is blocked by the incantation, 'trade secret,' " he said.

STANFORD--A proposed expansion of Stanford University's nursing school cannot be implemented at this time for financial reasons, Dean Clayton Rich of the School of Medicine, said Thursday (March 30).

Instead, the dean said, he is in the process of appointing a committee to recommend an appropriate role Stanford should play in nursing education.

He said shortening the present five-year nursing curriculum and training nurses for primary care roles was one of several options. Currently, Stanford offers a baccalaureate degree program in nursing. It leads to certification in public health nursing.

The nursing school recently announced it will not admit students to the five-year program until a new nursing curriculum is developed.

The proposal, which would have phased out the present program and created an autonomous graduate school of nursing, was contained in a 120-page document titled "Planning for the Future of Nursing Education at Stanford 1972-82."

The document was prepared for the Medical School by Dr. Kathryn M. Smith, dean of the School of Nursing of the University of Colorado, and Mrs. Betty J. Dietrich, former associate clinical professor of nursing at the University of California.

Their report recommended a 10-year development plan for a new graduate school of nursing with programs leading to the Master of Science and Doctor of Philosophy degrees. The program would have stressed training of nurses for research, faculty, and administrative positions in schools of nursing, training of nurse clinicians for direct-care roles, and continued education of nurses in the Stanford area.

Dr. Rich termed the proposal for setting up a new school "unrealistic" in view of other priorities and financial constraints facing the Medical School and the University at this time.

"But some of the stated goals in the report are attainable and desirable," he said. He cited the training of nurses to provide direct care as an idea worth exploring.

The study was sponsored by the U.S. Public Health Service and the San Francisco Foundation.

STANFORD--Robert G. Lindee, assistant to the vice president for medical affairs and associate dean for administration at the Stanford University School of Medicine, has been appointed vice president of the Henry J. Kaiser Family Foundation.

Appointment of the 43-year-old medical school executive was announced today by George D. Woods, chairman of the charitable and grant making trust, and by Dr. Robert J. Glaser, who earlier this month was elected the Foundation's first full-time president. Glaser, currently vice-president of the Commonwealth Fund in New York, was formerly dean of the Medical School and acting president at Stanford.

Both Lindee and Dr. Glaser will take office on July 1.

Lindee, who has been at Stanford since 1965, is also executive director of the Sun Valley Forum on National Health, Inc., and serves as consultant to several National Institutes of Health Advisory Councils, including the National Cancer Institute, the Bureau of Health Manpower, the National Eye Institute, and the National Environmental Health Sciences Institute.

He is also a member of various committees of the Association of American Medical Colleges and was a member of the first Executive Committee of the Business Officers' Section of the Association.

At the state level, Lindee is a member of the California Medical Student Contract Advisory Committee (Scholarship and Loan Commission), and has served as a member of the California Ad Hoc Committee on Teaching and County Hospitals.

Prior to coming to Stanford, Lindee was associated for two years with Dr. Glaser when he was president of the Affiliated Hospital Center at Harvard Medical School. From 1959 to 1963 he served as executive assistant to the vice president for medical affairs and dean of the University of Colorado Medical School in Denver. While at the University of Colorado, he also was administrator of the Western Interstate Commission on Higher Education's Dental Grant Program.

He holds Bachelor of Arts degrees in Psychology and in School Administration from the University of Colorado at Boulder.

At Stanford, in addition to his other duties, he has served as president of the Faculty Club, and has served on numerous University committees. He has also been secretary of the executive committee of the Medical School Faculty.

Lindee was born in Denver. He is married to the former Marjorie Anne Frame. They have three children and reside on the Stanford campus. ### Mailed March 29, 1972

STANFORD--Scientists at Stanford University School of Medicine are developing a computerized system for diagnosing heart disease which may be instrumental in mass screening of the American population.

"Our basic goal is to develop a research-validated, fully-automated method to conduct mass screening of the population as to cardiovascular risk," said Dr. Jobst von der Groeben, director of the project and professor of anesthesia and medicine at Stanford.

Heart disease, the leading cause of death in this country, kills over 600,000 Americans per year. Computerized diagnosis and screening, von der Groeben believes, could help prolong or save the lives of many potential victims of this "epidemic."

"You don't need a computer to diagnose the later stages of heart disease, when a patient comes in with a crushing pain in his chest," he said. "We're interested in detecting the early symptoms of coronary artery disease. In this area, advanced methods of data acquisition and mathematical and statistical analysis are essential."

Stanford is currently utilizing computers to analyze electrocardiograms (recordings of the heart's electrical activity) and aid in the diagnosis of selected groups of heart patients. Von der Groeben estimated that fully-computerized diagnosis of heart patients could begin on a routine basis after approximately three more years of research validation.

"We don't want to merely mimic the high error rate in human interpretation of a patient's electrocardiogram (EKG)," he said. "In some instances the same EKG can be read and interpreted differently even by expert cardiologists. We want to use the computer to standarize the method of diagnosis at a very sophisticated level."

The system involves a preprocessing digital computer (designed specially for this project by Stanford research associate Robert Clappier), and a larger computer which undertakes the analysis.

The small bedside unit picks up the patient's heartbeat from chest electrodes, and converts heart voltage into numbers on a nine-channel digital tape. The tape is then fed into the larger computer for classification into statistical data.

In addition to the EKG, information on the patient's diet, exercise and smoking habits, blood fat levels, and family medical history is fed into the computer.

The computer then produces a diagnosis of the patient's heart condition. At present, this is in the form of a numerical and graphical display revealing how the patient deviates from the norm for his age and sex group. Eventually, the system will produce a diagnostic classification statement.

The whole process takes roughly four minutes of the computer's time. "Hopefully, this would mean that the screening program would be inexpensive enough so that everyone could afford it," von der Groeben said.

-more-

If a patient is found to be carrying a high cardiovascular risk, doctors can prescribe exercise, changes in diet, blood pressure regulation, and restrictions on smoking, von der Groeben noted. "These measures could prevent, or at least delay significantly, many heart attacks," he said.

Von der Groeben, a pioneer in the development of a mathematical method for analyzing EKG's, gave up his private practice in Manteca, California in 1966 to come to Stanford and devote full time to this project. He felt that this mathematical analysis could become a valuable diagnostic tool when applied by a high-speed digital computer.

The Stanford cardiologist began accumulating data for the project in October of 1969, when his team recorded the EKG's of 1,180 volunteers in Modesto, California. Each volunteer was also given a physical examination and blood test. Two months ago, the research team returned to Modesto and tested 1,400 volunteers, including 800 of the original 1,180 from 1969.

By building up a large, validated "normal" sample, von der Groeben was able to establish standard heart patterns for particular age and sex groups.

"You can't diagnose heart disease without knowing what a normal EKG is," he said. "The standard EKG rarely includes age and sex. But we find there is a statistically significant difference between normal male and female EKG's, and between young and old."

The re-testing of 800 volunteers after two years allowed the Stanford researchers to make the first longitudinal comparison of heart patterns of a large population sample.

"We want to determine how a person's EKG varies over a period of time," von der Groeben said. "We find changes in the male population beginning at age 35 which don't show up in females until age 50. These changes may be related somehow to the very large incidence of coronary artery disease in men between 40 and 60."

Working with von der Groeben in the Modesto study and in developing mass screening methods are Dr. John Farquhar, associate professor of medicine at Stanford, and Dr. Peter Wood, research associate in medicine. Farquhar is director of Stanford's Specialized Center of Research in Arteriosclerosis and Lipid Research Clinic; Wood is deputy director of both.

During the last Modesto study, Farquhar and Wood conducted a random study of 350 Modesto residents concerning the relationship of blood fat levels and behavioral traits (such as diet, exercise, and smoking) to heart patterns.

At the conclusion of the Modesto studies, von der Groeben sent full reports on all volunteers to their doctors.

The Stanford researchers may return to Modesto again in two years to continue their observations of individual heart patterns through time. "This will enable us to further evaluate the longitudinal aspects of cardiovascular risk prediction," von der Groeben said.

The project is being funded by the National Heart and Lung Institute.

Editors: Picture available on request.

STANFORD--When he is not serving food in the cafeteria of Stanford University Medical Center, dietary employee Salvador Ortega, better known as Alejandro Fontana, will most likely be found on stage acting or singing.

A native of Zacatecas, an ancient Indian town high in the mountains of central Mexico, Ortega studied acting in Mexico City. Under the stage name of Alejandro Fontana, he appeared in theatre, movie and television productions. After graduation from the drama school of the Mexican national artists association, however, the actor felt he needed broader experience.

In search of new opportunities, he came to Palo Alto last year. Although he uses his real name for official purposes, he prefers his stage name. To his fellow Medical Center employees and to anyone who has seen him perform, he is Alejandro Fontana.

Work in the cafeteria since last February has provided Fontana with two opportunities: to learn English and to study people. "As a person and as a performer I enjoy interacting with people as they come through the line. I talk to them, learn their ideas and watch their reactions," comments Fontana.

He feels that many of the Mexicans in this area do not appreciate their native culture. "Youngsters going to school here do not learn about Mexican literature or art, and older people who have been away from Mexico no longer remember their native traditions. I want to bring the traditions and culture of our country back to them," Fontana explains.

To do this, he has produced two plays, a classical play presented last fall in Redwood City, and a Christmas pageant shown December in San Jose. A comedy, "Rosalva y los Llaveros" by Mexican writer Y Carballido, will be presented in April in San Jose. These plays have given actor Fontana his first opportunity to direct and produce, and he considers the experience worthwhile.

"The real purpose of putting on the plays," says Fontana, "is to share my knowledge and love of Mexican theatre and life with others." They are a nonprofit venture and admission is charged only to cover production costs. He hopes to do more plays by native Mexican authors. -more-

222--Ortega Fontana

Alejandro Fontana is also familiar to many here and in Mexico as a singer. His interest in singing goes back to his early childhood when, before he could really talk, he would unabashedly climb up on the table and scream, he recalls. He was always singing in his free time, and even won some amateur contests as a youngster.

Now he sings on his days off for various functions when he is called. He prefers Mexican folk songs, but also sings in English, French or Italian, often accompanying himself on the guitar. For a few months last year, Fontana had a Spanish news and music program on channel 36. A record that he made, "Mi Distrito Federal" which is a song about Mexico City, sold well in this area.

Fontana also enjoys painting, another hobby he has indulged in since boyhood. He usually does portraits in oil or charcoal. Recently he has taken up Zapateado, Mexican folk dancing that involves rhythmic stamping. "When you're in show business, you never know what you'll be called on to do or what part you'll play next, so I just keep busy trying new things," says Fontana.

His family is still in Mexico, although his wife alternates her time between Palo Alto and Mexico City, but Fontana is not thinking of returning there yet. He thinks California is a beautiful place. "The weather is as nice as it is in Mexico, and the wine and apples are better."

STANFORD -- A lawsuit filed by a Berkeley environmental group and a Stanford University graduate student has compelled the Food and Drug Administration (FDA) to agree to release information about a controversial food preservative.

The suit, filed in U.S. District Court on February 3 by the Environmental Defense Fund (EDF) of Berkeley and Dale B. Hattis, a doctoral candidate in Stanford's Department of Genetics, requested the disclosure of scientific data about an allegedly harmful food additive known as sodium nitrite.

Sodium nitrite is used commercially as a color fixative and preservative in almost all hot dogs and other sandwich meats.

Yesterday (March 22), FDA assistant general counsel Peter B. Hutt promised that the information, previously withheld under a policy restricing public access to "trade secrets" submitted by manufacturers, would be released shortly. He also requested that the lawsuit be dropped.

Thomas F. Graff, the attorney representing Hattis and the EDF, agreed to withdraw the suit as soon as the long-hidden data has been made available.

Hattis, a former associate of Ralph Nader, was supported in the suit by Stanford's Nobel Prize winning geneticist, Dr. Joshua Lederberg.

Hattis and the EDF contended that many scientists have voiced concern that sodium nitrite can combine with other food elements to yield cancer-causing chemicals in mice and rats.

Editors: This is the first in a three-part series of articles dealing with heart disease and Stanford University Hospital's Coronary Care Unit.

Photos available upon request if not included with release.

STANFORD -- At first, Dick Lamb never suspected he was having a heart attack.

"For three consecutive nights I woke up after midnight with what I thought was indigestion," the 63-year-old Palo Altan remembers. "On each occasion I got up and sat down in my easy chair in the bedroom. Being upright seemed to ease the pain a little. I smoked a couple of cigarettes and went back to bed."

But on the third night, June 25, 1969, the pain didn't go away.

"After awhile I went back to bed, then I got up and smoked some more cigarettes, but the pain persisted," Lamb says. "As I sat there, I felt a numbness creeping down my arms. At that moment it hit me--I was having that dreaded thing called a heart attack."

At 3:00 a.m. the numbness had reached Lamb's fingers. He awakened his wife and told her of his suspicions. She called their physician, who asked the Lambs to go immediately to the Emergency Room at Stanford University Hospital, where he would meet them.

"I snuffed out my last cigarette, my wife packed me into the car, and we left for the Hospital," Lamb says. "I drove there in my pajamas."

Upon arriving at the Hospital, Lamb announced himself and found "they were expecting me." The treatment began immediately.

Emergency room nurses gave him medicines to relieve the pain (analgesics) and administered oxygen through a nasal catheter. His blood pressure, heart rate, and temperature were taken. Electrodes dabbed with conductive paste were attached to Lamb's chest so his heart rate and rhythm could be monitored.

After this preliminary treatment he was quickly taken to the Coronary Care Unit. Nurses there started an intraveous infusion of dextrose solution. This maintained an open line for emergency administration of medications if they would be needed. A central venous catheter was inserted to measure pressures and obtain blood samples. This provided doctors with helpful information relating to the functioning of the heart.

"They were well trained and well equipped to take care of me," Lamb recalls. "Soon my doctor, Dr. William Clark, arrived and assured me that everything would be okay if I followed all the rules. One rule he insisted on most strenously was that I stop smoking. I haven't had another puff since."

By late morning Lamb found that "the pain had disappeared." He spent a week receiving intensive treatment in the Coronary Care Unit. When his condition stabilized, he was moved to Cardiac Surveillance Unit, where he was treated for an additional two weeks.

Despite another attack in the September of 1971 ("I discovered you can get a heart attack for other reasons besides smoking"), he is now back at work as an associate editor of Business Week magazine in San Francisco.

-more-

Dick Lamb's experience is not an uncommon one. In the United States, coronary heart disease has become "an epidemic," in the words of Dr. John Farquhar, director of Stanford's Specialized Center for Research in Arteriosclerosis and Lipid Research Center.

The target of this epidemic is a hollow sack which weighs well under a pound and is only a little larger than a fist.

The heart is basically a muscle to pump blood throughout the body. A normal human heart beats regularly 60 - 80 times per minute. Special conducting tissues in the heart deliver an electrical current to the muscle and cause it to contract. This electrical action which triggers the contraction of the heart muscle is what is recorded on an electrocardiogram (EKG).

The heart pumps blood to body organs. The blood carries oxygen to the tissues and is used to convert food into energy. Being live tissue, the heart needs the same type of energy. It gets this energy from oxygen-rich blood cells delivered by coronary arteries.

The coronary arteries must bring approximately one pint of blood per minute to the heart throughout an individual's lifetime. They are called coronary arteries because they surround the base of the heart like a crown, and then extend branches downward to penetrate the heart muscle.

Coronary heart disease affects the inside or lining of these arteries. The buildup of fatty materials along the interior walls causes narrowing or obstruction of the arteries.

In a heart attack, more technically known as a myocardial infarction, these arteries are obstructed so that enough blood cannot flow through. An area of the heart is deprived of its necessary blood and oxygen supply, and damage or death results. (Myocardial refers to the heart muscle or myocardium. Infarction is the destruction of tissue which occurs when too little blood reaches it.)

Coronary heart disease affects between 10 and 12 million Americans and is the leading cause of death in this country. Far more common in men than women, it affects men between the ages of 45 and 60, in particular.

The disease occurs more frequently with age and is found rarely in persons under 20, although it now strikes increasing numbers of young adults.

In the United States, heart disease kills over 600,000 persons per year. Over one million work days are lost annually in this country alone.

At the present time, a North American man has about one chance in five of developing coronary heart disease before age 60, mostly in the form of a myocardial infarction. At least 25 of those experiencing a first premature heart attack die within three hours after the onset of symptoms, often prior to hospitalization and before receiving any medical care.

These sobering statistics have stimulated the establishment of Coronary Care Units in many American hospitals throughout the past several years.

STANFORD -- "The Coronary Care Unit is the kind of place you ought to avoid getting into," says Dick Lamb. "But if you get there, don't wring your hands in despair. You've got a lot going for you."

Lamb ought to know. Twice he's been a patient in the Coronary Care Unit at Stanford University Hospital after suffering a heart attack. Despite his two attacks, the 63-year-old Palo Alto resident is now back at work as an associate editor of Business Week magazine.

The concept of the Coronary Care Unit (CCU) was born in the mid-1960's, when many medical centers across the country decided to try to do something about the increasing mortality rate due to coronary heart disease. Studies had shown that if a person survived a heart attack long enough to be admitted to a coronary care area staffed with trained personnel and equipped with electronic monitoring instruments, his chances of survival would be dramatically increased.

"Most of the deaths from heart attacks occur within the first few days," Dr. Alfred P. Spivack, director of Stanford's CCU, said at its opening in 1966. "Experience indicates that prompt and effective treatment in the hospital will significantly reduce this mortality."

Over the past five-and-a-half years, this theory has been borne out in innumerable cases. It is estimated that the in-hospital mortality rate due to heart attacks has been cut in half by the advent of CCU's. The mortality figure for patients admitted to a CCU has dropped to under 20 per cent.

Furthermore, cardiologists believe that many additional lives could be saved if more patients recognized the first symptoms of an attack and came to the hospital without delay. A majority of the 600,000 persons who die annually from coronary heart disease do not reach the hospital.

In the CCU, electronic monitoring equipment enables physicians and nurses to constantly observe a patient's heartbeat on an oscilloscope at the nursing station, or on a screen at the patient's bedside. Automatic alarm signals alert the staff to any change in cardiac rhythm or rate. In the event of an emergency, staff members are trained to immediately initiate cardiac resuscitation or defibrillation.

Primarily, the CCU is designed to care for patients who have been stricken with acute myocardial infarction, heart block, or severe heart failure due to other causes. All require intensive observation and treatment, and possible emergency resuscitation.

The average patient stay in Stanford's CCU is five days. Over 2,200 patients (or about 34 per month) have been treated in the CCU since it opened as a four-bed unit on September 26, 1966. Two additional beds were added in 1968.

"We now have four beds monitored in direct view of the nursing station," says Dr. Spivack, "and two beds with television monitoring. Our equipment has the capability for measuring electrocardiographich changes and one other parameter, such as blood pressure or pulse, from the patients' beds."

-more-

Mailed March 24, 1972.

During the past few years, Stanford's CCU has attempted to expand the intensive treatment brought to the bedside of heart patients. More and more patients are being treated in the CCU for complications of myocardial infarction, degenerative heart disease, and aneurysms (weakening and stretching) of the ventricle.

"We're moving into the second generation of coronary care units," Spivack says. "The first stage in CCU development was recognizing acute changes, preventing fibrillation (random, uncoordinated contractions of the heart muscle, responsible for the majority of sudden coronary deaths), and early treatment of irregular rhythms. Prior to the advent of the CCU, patients often died during the night in quiet rooms.

"Now we're entering the second phase. The deaths we have now in CCU are often related to shock and heart failure. We have to recognize and treat this earlier."

The entry into the "second generation" of coronary care units has been accompanied at Stanford by the development of a special multi-purpose treatment room. CCU staff can use the room to perform cardiac procedures such as the insertion of pacemakers, as well as for teaching purposes and conferences to discuss patient therapy.

A special wall panel in the room has oxygen and suction outlets, compressed air, and resuscitation equipment so that a patient can remain overnight. This, in essence, provides Stanford with an additional short-term CCU bed.

"The advantage is that we can do various procedures right in this room without moving patients from the coronary care area," says Jan Gross, special procedures nurse. "In addition, we'll be doing some new things like studying electrical conduction within the heart to see if a person needs a pacemaker."

One of the most important uses of the room will be the treatment of patients suffering from shock.

"We plan to monitor patients while we're giving them therapeutic drugs for the treatment of shock," Miss Gross says. "We can insert catheters to measure how well the heart is functioning, whether a patient is coming out of shock, if a particular drug is working, or if we should consider using another drug."

To do a better job in the treatment of CCU patients, doctors are attempting to devise better techniques to measure heart function and detect early warning signals of impending fibrillation or cardiac arrest. Cardiologists at Stanford, including Spivack, Dr. Donald Harrison, chief of cardiology, and Dr. Jobst von der Groeben, professor of anesthesia and medicine, are working with computer programmer Bill Sanders on computerized detection and evaluation of changes in heart rhythm.

"It is important to recognize different heart rhythms and correlate them with different cardiac functions and changes," Spivack says. "This will give us an idea of how aggressively to treat these arrythmias."

Another detection method, developed at Stanford's CCU, is called venous oxygen saturation. CCU nurses obtain a qualitative measurement of heart function on the basis of how much oxygen is extracted from the blood by body tissues.

A new dimension was added to Stanford's treatment of heart patients in mid-1970 with the establishment of a new Cardiac Surveillance Unit, adjacent to the CCU. In this unit, a centralized monitoring console in the nursing station keeps watch over eight patients simultaneously.

Funds for equipmment in the surveillance unit, as in CCU, were provided by a gift from the Medical Center Auxiliary.

All 28 beds in the unit (located in the West IB wing of the Hospital) are equipped with monitoring capabilities, so any eight of the beds can be connected to the main console at one time.

"The surveillance unit has given us greatly increased flexibility," Spivack says. "Patients who need monitoring, particulary in an emergency situation, do not have to be moved since all the beds can be monitored."

-more-

Patients are admitted to cardiac surveillance when they are being evaluated for cardiac surgery, if CCU is full, or if their condition is not serious enough to merit admittance to CCU. In many cases, however, a patient is moved to cardiac surveillance from CCU after his condition has stabilized.

"The surveillance unit is a logical extension of the smaller CCU adjacent to it, where patients require more intensive treatment," Spivack says. "It is also consistent with our philosophy of a graded care system. In the surveillance unit there is a program of gradual and continual healing, and phasing back into normal activity."

A key feature of cardiac rehabilitation is an in-hospital exercise program, developed at Stanford, designed to prevent complications of inactivity. The tone of muscles and blood vessels is often lost during extended bed rest. Prolonged immobility can also result in joint stiffness, and slowing of the circulation can lead to increased blood clotting. The exercises, which do not require the patient to expend any more energy than is required to roll over in bed, are organized and prescribed so that specific muscles are utilized. They are taught to the patients by the nursing staff.

Once they leave Stanford Hospital, many heart patients begin an exercise rehabilitation program at the Palo Alto YMCA. This exercise plan, under a doctor's supervision, is open to those who have a history of coronary heart disease and are referred by their doctors.

The workouts are supervised by Dr. Gary Fry, cardiologist at Stanford and Palo Alto Medical Clinic. Fry, who exercises along with the patients, says that one of the aims of the program is to show that endurance exercise can lower the death rate and prolong the lives of patients with heart disease.

The treatment of heart patients at Stanford has also been aided by the advent of a coordinated cardiology service from the School of Medicine. Until a few years ago, this teaching service did not exist. Now, two interns, two residents, and up to six students are assigned to cardiac surveillance and CCU.

"For the patients, it may appear that they're seeing a lot of people," Spivack says. "But there's always someone close by who knows them and can treat them in an emergency. The result is that patients are getting better care from a lot of very interested people."

The rendering of 24-hour-a-day care makes the CCU an expensive unit to maintain at peak efficiency. The unit staffs one specially-trained nurse for each two patients. Highly sensitive equipment must be continually updated, and new advances in the detection and treatment of heart disease must be implemented.

"Since the concept of coronary care units is relatively new, we're just beginning to come to the end of the line for our present equipment," says Sue Brueckner, nursing service administrator. "All the monitors we have now are the original ones we started with in 1966. Their life span is a little over five years, so we'll have to begin replacing them soon."

The cost of one complete electronic monitoring system is approximately $1,800.

"In two or three years we're projecting a budget of nearly $100,000," Miss Brueckner continues. "Cardiology is rapidly expanding. We need to be constantly updating equipment as well as modernizing the unit with new types of instruments that are being developed."

One such instrument system, telemetry, will enable doctors to monitor patients not just at their beds but as they begin to ambulate in the hall, says Dr. Spivack. Resembling a transistor radio, the portable monitoring system will be carried in the patients' shirt pocket or in a leather case on a shoulder strap.

The financing of new equipment such as the telemetry system is only part of the money problem faced by CCU and cardiac surveillance. The ever-increasing demands for intensive treatment of heart patients has created a need for additional space in many CCU's, including Stanford's.

"Now we can do all the things necessary and do them well," Spivack says, "but our expansion in treatment and diagnostic capabilities has created a greater need for space.

"The growth of coronary heart disease to epidemic proportions has greatly increased our need for beds, equipment, a testing area to aid in rehabilitation and diagnostic studies, and a special treatment room for patients with shock. We need two more beds in CCU on a routine basis. But this, as

Editors: This is the third in a series of articles dealing with Stanford Hospital's Coronary Care Unit. Pictures available on request if not included with release.

STANFORD--"It's an exciting place to work," says Joan Fair, clinical nursing coordinator of the Coronary Care Unit (CCU) and cardiac surveillance unit at Stanford University Hospital. "You have to be prepared to act on a moment's notice. Psychologists have referred to us as 'the green berets of nursing.'"

For the CCU nurse, emergencies are commonplace. With the possibility of a fatal cardiac arrest present at all times, a moment's hesitation could be disastrous. Nurses in CCU must be able to recognize early warning signals and deal with them immediately.

"Technically, our nurses need to know how monitors, oscilloscopes, defibrillators and pacemakers work, but there's much more than that," Mrs. Fair says.

"We have to recognize threatening electrocardiographic patterns and take appropriate actions, such as resuscitation or defibrillation, without even the slightest delay. We must recognize normal and abnormal patterns and relate them to disease pathology."

The image of the nurse as waitress-maid-custodian has long been antiquated, and nowhere is this more apparent than in Stanford's CCU.

"We're taking on tasks physicians used to do, like inserting central venous catheters," says Mrs. Fair. "In most hospitals, nurses don't do this. Here it's part of our training. Most of our nurses are expert at reading and interpreting electrocardiograms.

"We're involved in diagnosing not only arrhythmias (abnormal heart rhythms), but infarction as well. Since the nurse is the one most often with the patient, she is encouraged to use her scientific knowledge to assess the patient's condition and to observe and participate in skilled examinations, such as listening to heart sounds."

To prepare them for the demands of working in these units, all nurses from West 1B (where CCU and cardiac surveillance are located) are required to attend a special five-day training course. The emphasis is on training the nurses to care for patients with myocardial infarction. The course consists of lecture and review sessions covering anatomy of the heart, physiology and pathophysiology, plus two days of on-the-job training on a one-to-one basis.

Stanford works in conjunction with three other local hospitals--El Camino, Mills Memorial, and Peninsula--in offering this course. It is given once every two to three months to a group of about 30 nurses from the four hospitals. Each hospital gives the course once or twice per year.

It costs Stanford an estimated $800 to send one nurse through the course, including in-class time, on-the-job sessions, and materials.

-more-

Generally, nurses work on West 1B for up to three months and spend a few days as an extra nurse in CCU before taking the course. Additionally, before registering potential CCU and cardiac surveillance nurses for the course, Mrs. Fair asks for a verbal commitment that they will remain in these units for at least six months.

"I feel it takes a person three months to become a useful, functioning member of the nursing team here," she says.

Increasingly, CCU and cardiac surveillance nurses have to deal with the psychological effects of heart disease. An attack or other disabling heart condition can take a tremendous toll on a patient and his family.

"You might have a patient of 50 who's had a heart attack," Mrs. Fair says. "He's known people his age who have died from it. He may have a son to put through college, or a house not paid for, or he may be the president of a company in the prime of his career. If he wants to know if he's going to die, you have to know how to deal with that. If you can't you shouldn't be a CCU nurse.

"A person who has an attack will not be able to return to work for some time," she continues. "He may have to work part time when he returns, or he may not be able to go back to work at all. Our goal is to return patients to their jobs about three months after their attack."

To many CCU nurses, these psychological ramifications of heart disease present a welcome challenge.

"Studies show that CCU nurses are frustrated pediatric nurses," Mrs. Fair smiles. "They really like mothering patients. They're not totally task oriented. They learn to help patients deal with both the emotional and physical aspects of their illnesses."

Stanford's CCU staff believes a patient can better adjust to his illness by learning more about it. Additionally, cardiologists at Stanford and elsewhere across the country are convinced that more widespread education regarding risk factors and symptoms of coronary heart disease can help combat the disease and reduce mortality.

"We're interested in patients learning as much about the disease they have as possible," Mrs. Fair says. "Most of them have had a heart attack or symptoms of it, or they are being evaluated for cardiac surgery. In every case, whatever we can teach them about their condition will be helpful.

"We've been giving classes here at night for some of our patients and their spouses to explain what a heart attack is, what the healing process involves, and what some of the risk factors, such as diet, are."

This education program, like everything else in CCU and cardiac surveillance, is designed to save lives. That, of course, is what it's all about. Dick Lamb, twice a patient at Stanford Hospital after suffering heart attacks, readily attests to the almost routine nature of life-saving in these units.

"When I was in cardiac surveillance the first time, I remember waking up and hearing something like 'Code 66,'" he says. "After that I heard the pitter-patter of feet outside my room several times. I asked a nurse what this was and found out it was the signal for cardiac arrest, and for all hands to get around the patient and try to bring him back. While I was there they brought them all back."

STANFORD--"A trained environmental extension agent could potentially do more for ghetto community health than a doctor or a nurse," an expert in environmental medicine said Wednesday (March 22) at Stanford University.

Addressing a symposium on health and housing, Dr. Elihu Richter of Mt. Sinai School of Medicine in New York City, said the many of the environmental problems in the ghetto community are caused by a breakdown in housing maintenance.

He outlined his work with a city group to involve local residents in the health and safety of their environment by training them to maintain their tenements.

The group involves the Mt. Sinai School of Medicine and the East Harlem Environmental Extension Service, a coalition of neighborhood housing groups, tenants and owners.

Trainees learn such specific repair tasks as plumbing, boiler upkeep, rodent and pest control, painting and plastering, and the relations of such maintenance to certain health problems.

The training program, Dr. Richter said, has shown that tenants and owners can work together for neighborhood health.

The program is funded by a pilot grant from New York State, and Dr. Richter feels it may serve as a model of a publicly subsidized way to deliver environmental health services to a community.

Dr. Richter made his remarks at the opening of a two-day symposium on Epidemiological Aspects of Housing, sponsored by Stanford' division of preventive medicine, and the California State Department of Public Health. Some 20 leading experts in the fields of housing and public health are taking part at the meeting which concludes Thursday (today).

STANFORD -- Complications of shingles infection in patients with Hodgkin's disease and other cancers may be related to a basic defect in interferon production, a Stanford University medical research team reported Thursday (March 23).

Interferon is a natural antiviral protein produced by human cells. It is believed to be effective against a broad spectrum of viruses.

Shingles, known by its scientific name as herpes zoster, is a viral infection in which patients develop blisters which follow the course of nerves. The inflammation is accompanied by severe pain, and can be localized or disseminated throughout many parts of the body.

The significance of the finding, the Stanford researchers said, is that it points the way to "possible approaches" in the treatment of shingles in Hodgkin's and other patients.

These would include use of drugs which stimulate interferon production, or giving patients white cell transfusions to increase the amount of the antiviral protein in their systems.

The Stanford researchers are Dr. David Stevens, and Dr. Thomas C. Merigan of the Department of Medicine. They reported their findings at an international symposium on Hodgkin's disease being held on the Stanford campus.

The investigators studied Hodgkin's patients with shingles and found an increasing lag of interferon production as this complication progressed and reached its peak.

When the patients began to recover from the inflammation, studies showed their cells had resumed normal levels of interferon.

"This suggests," the researchers said, "a potentially important role for local interferon in host defense against viral infections."

The problem of disordered cellular immunity is a common denominator in a variety of situations in which normally mild viral infections become progressive and even lethal.

However, this is the first time important evidence of the role of interferon resistance to infection has been studied in patients with Hodgkin's and other cancers which impair the body's immune system.

The finding also goes beyond this common complication in cancer patients. Herpes zoster also affects patients who have received kidney or heart transplants because of the drugs they receive to control graft rejection.

The Hodgkin's disease symposium will continue through Friday. It is supported by the International Union Against Cancer and the National Cancer Institute.

Nearly 150 scientists from the U.S. and abroad are taking part.

Tomorrow's sessions will be devoted to conclusions and research and treatment goals for the future.

STANFORD--Stanford University Hospital and American National Red Cross officials today (March 22) signed an agreement to establish a new blood center near the Stanford Medical Center.

The new center, scheduled for opening in July, will include two components--the Palo Alto Red Cross Sub-Center, a blood collecting and processing facility; and the Stanford University Blood Center, designed for research, teaching, and clinical care functions.

The Palo Alto Sub-Center, a satellite branch of the Four Counties Red Cross Blood Bank in San Jose, will supply Stanford Hospital with the major portion of its blood needs.

"Progress in the science of blood banking and in the use of blood components in therapy has made it essential for us to join with Red Cross in the establishment of this new blood center," said Dr. Thomas A. Gonda, hospital director.

Dr. Gonda said the new center will provide improved facilities for patient care, training future physicians and specialists, and research into the fields of immunotherapy, coagulation, and tissue-typing.

"This type of venture also gives us a starting point for potential exciting developments in the banking of tissues other than blood," he added.

The agreement was signed at Stanford Hospital by Dr. Gonda and Dane Christensen, chairman of Red Cross' Central California Regional Chapter (CCRC). Also signing for Red Cross was Roscoe Whatley, executive director of the CCRC.

The new center will be located in a 12,000 square foot building at 3330 Hillview Avenue, in Stanford Industrial Park.

Renovation of the building, which formerly housed offices of Control Data Corporation, will begin within 30 days. The Red Cross Sub-Center will occupy 6,000 square feet, and 3,000 square feet will be alloted to Stanford's teaching, research, and clinical functions. The remaining 3,000 square feet will be reserved for future expansion.

The blood center will be established in four phases, said Dr. Stanley Schrier, head of the division of hematology at Stanford.

Phase 1 calls for the establishment of the Red Cross Sub-Center to accommodate Stanford Hospital's increased need for blood. Stanford's kidney transplant and cardiovascular surgery programs alone now require more blood than was needed for the entire hospital 10 years ago.

Under phases 2,3, and 4, centers for tissue-typing, coagulation, and immunotherapy will be established.

Additionally, a blood freezing program will be initiated sometime during the first year of the center's operation. The Red Cross uses an advanced method of processing frozen blood. Its chief use will be for storage of rare types of blood.

"We predict that the center will draw 8,000 units of blood during the first year of operation, with about half broken down for use as components," Whatley said.

He said the new center is being designed as a model blood bank with the latest in equipment and facilities.

STANFORD--Evidence suggesting a link between viruses and Hodgkin's disease, and possible hereditary predisposition of some people to this form of cancer highlighted the opening session Monday (March 20) of a five-day international meeting at Stanford University.

Until now various laboratories have reported associations between viruses and cancer of the breast, the cervix, and Burkitt's lymphoma, found widely among children in Uganda, Africa.

But this was the first time the international panel began to look at Hodgkin's disease from a new point of view--namely that the initial damage was done by a virus.

Hodgkin's disease affects the body's lymphatic system and kills some 4,000 people in the United States each year. If caught early, the disease can be treated successfully with drugs and radiation in 80 percent of the cases.

The cause of the disease is unknown. But a person who has a close relative with Hodgkin's disease is three times more likely to get it. And recent reports of possible transmission from one person to another have suggested that a virus or viruses may be involved.

The infectious agents in question are the EB virus and various other herpes viruses. The EB virus has been implicated as a cause of Burkitt's lymphoma. Type 1 herpes causes cold sores. Type 2 is found in the genital tracts of adults and is considered a venereal infection. It is a key suspect in the origin of cancer of the cervix.

Although any association between these viruses and Hodgkin's disease remains tentative, the scientists at Monday's meeting agreed there should be more work done on what these viruses are and the disease they cause.

Among those reporting the presence of virus-like agents from patients with Hodgkin's disease was Dr. F. Kingsley Sanders, a virologist with the Sloan-Kettering Institute for Cancer Research in New York.

He said cultured cells from patients with Hodgkin's disease were found to undergo changes accompanied by the release of an agent tentatively identified as a member of the herpes group.

-more-

222--Hodgkin's Disease

Dr. Paul Gerber, a scientist with the Division of Biologics Standards of the National Institutes of Health, said his studies could not confirm that the EB virus causes cancer in man.

But, he went on, the EB virus possessed unique biologic properties associated with known cancer-causing DNA viruses.

Another scientist, Dr. Werner Henle of Children's Hospital in Philadelphia reported on studies showing an association of EB virus to infectious mononucleosis, commonly known as "the kissing disease " from the way it is transmitted among young adults.

Similarly, Dr. Henry S. Kaplan of Stanford University reported that 50 of 250 patients between 15 and 35 years of age, who were treated at Stanford for Hodgkin's disease in recent years, had a previous history of infectious mononucleosis.

This evidence does not support a causal relation of infectious mononucleosis to Hodgkin's disease, Dr. Kaplan cautioned, but points the need for a prospective study.

If Hodgkin's disease is caused by a virus why isn't the disease more widespread? Because, as in any other infectious diseases, most people develop immunity to it.

Curiously, however, a substantial number of patient s with Hodgkin's disease showed impairment of their immune response system, several scientists reported. Whether this impairment begins before or after the onset of the disease is not clear.

Dr. Walter Bodmer of Oxford University suggested that susceptibility to the disease may reflect the activity of scores of a person's genes. Some of these immune response genes were recently identified by scientists at Harvard and Stanford, and have led to several studies in England, France, and Australia which point to an association between heredity and Hodgkin's disease.

"The effect of the genes may simply be to increase or decrease the probability of getting the disease, for example through an effect on the individual's susceptibility to a virus," Dr. Bodmer said.

Other scientists presented reports on the epidemiological aspects of Hodgkin's disease, which appears generally to be more prevalent among populations in warm climates, and people of low socioeconomic levels.

There was a consensus, however, that epidemiological data from some underdeveloped countries were uneven, and in need of evaluation.

The Hodgkin's disease symposium will continue through Friday. It is sponsored by the International Union Against Cancer and the National Cancer Institute. Nearly 150 scientists from England, France, Israel, Japan, Italy, Norway, Sweden, The Netherlands, U.S., and West Germany are attending.

Heart Transplant Patient #41

STANFORD--Stanford University Hospital surgeons performed a heart transplant operation Friday afternoon (March 17) on a 51-year old California man. He is listed in satisfactory condition.

The operation was performed by a team headed by Dr. Norman Shumway.

Hospital policy has been to withhold names of heart transplant patients if they so request. In this case, the recipient requested anonymity.

Including the new recipient, 15 of the 41 heart transplant patients operated on at Stanford are now living.

STANFORD -- Stanford medical students will no longer put up with monkey business from drug companies, which, the students claim, will sink to any level to sell their products.

To draw attention to the problem, the Stanford Medical Students Association (SMSA) sponsors a contest among students, faculty, and employees at Stanford University Medical Center.

Called "Absurd Drug of the Month," the contest invites persons to send in advertisements that have appeared in recent medical journals to get doctors to prescribe certain products.

This month's winning entries are laxative ads, one showing a happy face and the other two chimps dressed in nightgowns.

The ads won the honor because, according to the students, they are dedicated to the great American obsession, "the daily bowel movement."

Winning ads are put on a display board outside the student lounge, with a disclaimer that SMSA "does not endorse any of the products."

The "happy face" ad is titled "Happiness is often as simple as a normal bowel movement."

It appeared in M.D., a medical magazine. The chimp ad was published in the prestigious California Medicine, the journal of the California Medical Association. The ad shows Mrs. T. Farnsworth Lipp, preparing to administer the usual teaspoon of laxative to junior before bedtime.

"And junior thinks - - - tastes so much like bananas that I never worry about a slip between spoon and Lipp," the ad copy goes.

Such drug promotion for doctors is absurd, the students think. According to Consumers Union, wrote Stephen Bezruchka who runs the contest, "no organ of the body is so misunderstood and maltreated as the digestive tract.

"It has been purged, irritated, lavaged, massaged and pummeled, all in the name of the great American obsession, 'The Daily Bowel Movement.' "

Bezruchka said the "Absurd Drug" idea serves to point out "the incredible extremes and expenses of drug promotion whose costs are passed on to the sick by the so-called 'ethical' pharmaceutical companies."

Judging from the number of contestants, the competition is a success, the student said.

The ad that aroused the greatest reaction among students and faculty appeared earlier this year. It showed a young woman being interviewed for a job.

"Before you hire her, make sure she is not pregnant," the ad admonished. The product--a pregnancy test kit.

Some people do not always agree with the selections, Bezruchka explained.

When a two-page, full-color ad of a bikini-clad blonde promoting a steroid drug was displayed, someone, presumably a drug company detail man, was seen removing it from the board, he said.

In this week's display, graffiti by an anonymous critic appears above the monkey business ad. The writer argues, tongue-in-cheek, that the ad is basically honest.

"They actually tested their laxative on chimps and they are afraid to extrapolate their data to humans," he wrote.

SMSA treats all winners to a free natural food lunch. ### Mailed March 15, 1972.

FOR FURTHER INFORMATION CONTACT: Hali Wickner 415: 321-5310

STANFORD -- Some people looking for an encounter group really need a psychotherapy group, according to a Stanford University psychiatrist.

Many people regard psychotherapy groups and encounter groups as synonymous and contact Bay Area mental health services asking for an encounter group experience, said Dr. Irvin Yalom. He is associate professor of psychiatry and director of the group therapy program at Stanford.

Although therapy and encounter groups may use similar techniques, the two are designed for different purposes, he said.

Author of a recent book and numerous articles on group therapy, Yalom cautions against confusing the goals of therapy and encounter groups. Encounter groups can provide worthwhile experiences or new methods of interacting with others. However, they can be disastrous for persons who unrealistically expect them to solve problems that may require long term follow-up. Severe problems, Yalom said, should be worked out with the help of professionally trained individuals in a psychotherapy group.

"A psychotherapy group concentrates on helping individuals work out personal problems. It meets regularly over a considerable period of time to provide the continuity necessary to explore problem areas of each member. An encounter group on the other hand is a short-lived, often intensive group which focuses more on sheer experience rather than change," he explained.

Yalom feels that those genuinely in need of help should be in a traditional psychotherapy group. Recent evidence also indicates that such individuals are the ones most likely to be hurt by an encounter group, which cannot accomplish in a few weekends what a therapy group does over a period of months or years.

Stanford Medical School has a large group therapy program readily accessible to the community. When people call requesting an encounter group, the psychiatrist on duty attempts to determine their needs. After the initial screening, potential group therapy candidates are further evaluated at the Medical Center by Donald Staight, a psychiatric social worker and administrator of the group therapy program.

-more-

March 13, 1972.

When indicated, some patients are referred out to other therapy groups run by private practitioners, social agencies, or mental health clinics. Those placed on the psychiatry clinic group therapy waiting list are assigned to newly forming groups or existing ones that have openings. Assignments are made only after careful consultation with the group therapists.

"It is important to fit the person to the group and the group to the person," said Staight. "There may be a waiting list, but it is never very long, since we will form a new group whenever we have enough people to work together. Our primary interest is to meet the needs of the community," he added.

The Psychiatry Department runs from 15 to 20 groups, including special ones for couples with marital problems, parents of disturbed children, or adolescents. Stanford is a nationally known center for group therapy training and all groups are led by faculty members or resident psychiatrists under the supervision of senior clinicians.

Fees are based on a sliding scale according to the patient's ability to pay. Meetings are held once or twice a week late afternoon or early evenings in one of the six group therapy rooms of Stanford's new Psychiatry Clinic Building.

Patients with an acute situational crisis are usually better off in individual therapy sessions. Most psychiatric problems, however, involve relating to or dealing with other people. Psychiatrists believe that group therapy is a logical and effective treatment for such problems.

The group therapy situation creates a mini-community in which there are a wide spectrum of ages and problems. Individuals, over a period of time, begin to experience what psychiatrists call their "out-there" problems within the confines of the group.

Therapists and patients have an ongoing commitment to the group. The therapist also has a continuing responsibility to every patient. If the therapist recognizes that a patient needs additional support or medication, appropriate measures are taken at once.

CITY DESKS AND SCIENCE WRITERS

STANFORD -- An international symposium on Hodgkin's Disease will be held at Stanford University March 20 through 24, 1972.

Experts from 11 countries will meet to pool their knowledge and talk about development and use of the best methods needed to conquer the disease.

Hodgkin's disease affects the body's lymphatic system and kills some 4,000 people in this country each year. Many persons, including physicians, tend to view the illness with an attitude of pessimism that is no longer warranted by the facts, said Dr. Henry S. Kaplan of Stanford University, a pioneering cancer researcher and chairman of the symposium's organizing committee.

Furthermore, many doctors continue to treat it by methods that specialists consider to be old-fashioned and often inadequate, Dr. Kaplan said.

Marked progress in diagnosis, as well as treatment, have contributed to the new outlook. Dr. Kaplan, as well as several groups including the National Cancer Advisory Council, the National Cancer Institute, and the American Cancer Society, have attempted to make known the possibilities of prompt and proper treatment.

Scientists have estimated that about 80 per cent of patients in whom the disease was found in an early stage were curable.

"We now see the beginning of important advances in epidemiology and causation of the disease," Dr. Kaplan said. The main sessions will focus on the relationship of Hodgkin's disease and viruses or, as Dr. Kaplan put it, "the biology of Hodgkin's disease."

Other topics scheduled for review include: immunological aspects, diagnostic methods, and treatment techniques.

In additon to U.S. representatives, participants from England, France, Israel, Japan, Italy, Norway, Poland, Sweden, the Netherlands, and West Germany will attend.

Dr. Kaplan said that much of the progress in treatment in recent years has been aided by these international meetings which began in 1965 in France, and subsequently held in London and Ann Arbor, Michigan. Stanford was chosen as the meeting site this year to commemorate the fact that the first clinical trials for treatment of the disease began at Stanford in Spring, 1962.

The symposium is sponsored by the International Union Against Cancer, and the National Cancer Institute (NCI). Members of the organizing committee include Dr. Ronald F. Dorfman, Dr. Saul Rosenberg, both of Stanford; and Dr. Gregory O'Conor of the NCI.

The meetings will be held at Tresidder Memorial Union starting at 9:00 a.m., Monday, March 20.

Science writers are invited. A press room has been set up at Tresidder Memorial Union, Room 205, (ASSU office). Papers or abstracts will hopefully be made available by the scientists at the meeting, and copies will be distributed to those who are interested. Copies of the program are available on request, if not included with release.

Editors: In an interview with the Stanford Medical Center News Bureau today (March 9), Dr. Donald C. Harrison, chief of cardiology at Stanford, provided the following background information relating to the experiment in which a patient will transmit his electrocardiogram 51,000 miles. (See earlier News Bureau story.)

STANFORD -- "Today we plan to demonstrate that this small monitoring device can accurately transmit an electrocardiogram over long distances by phone. This is a very important characteristic of such a detection and warning system, since it allows the user to relay his EKG to his doctor from a remote location. It gives the patient the opportunity to consult with the physician and then take appropriate action.

"However, clinical trials to demonstrate its effectiveness in detecting life-threatening arrhythmias and warning patients have not been completed or documented.

"We felt that a public demonstration of this type of monitoring system was necessary to call attention to the epidemic of sudden cardiac death in this country and the efforts being made to prevent it.

"Sudden cardiac death is one of the biggest health problems in the country right now. Of patients who have heart attacks each year, approximately 150,000 die suddenly before they reach a hospital.

"Although we have good therapy in hospital coronary care units for preventing death due to cardiac arrhythmias (abnormal heart rhythms), we have no way to diagnose and treat these arrhythmias outside the hospital.

"Additionally, although cardiologists have suspected for years that these patients have premonitory arrhythmias prior to the fatal arrhythmia resulting in sudden death, it has not been possible to document this with certainty.

"In the past few years, however, results of investigations utilizing tape recorders to monitor heart patients have suggested that these people do have warning arrhythmias which they may not recognize themselves.

-more-

"To diagnose and make a clinical study of this, several advances for detecting abnormal heart rhythms on ambulatory patients going about their daily activities have been developed. It is now possible to pick out patients who are in a high-risk group and use these techniques on them.

"To attest to the value of such methods, it should be noted that of people who die suddenly, half have seen their doctor in the previous week. So they know something is coming on.

"The first technique utilizes a small tape recorder for continuous recording of heart action. This tape can be worn by a patient and then returned to the hospital for analysis by cardiologists, or at some medical centers, by a computer.

"The second technique involves the same type of tape recorder unit, but the patient only turns it on when he suspects an arrhythmia. He then brings in the tape for analysis.

"The third method is to wear a small device which continuously monitors heart activity, detects abnormal rhythms, and sounds a warning, like the device we will test today.

"All of these techniques are now in the evaluation phase. Additionally, a great deal of clinical research is being carried on to attempt to validate the concept that people do have premonitory arrhythmias prior to the fatal arrhythmia.

"If, indeed, people do have these promonitory arrhythmias, and they can be detected outside the hospital, the administration of therapeutic drugs may help prevent the fatal arrhythmia. There are a number of anti-arrhythmic drugs which can be used in such therapy.

"Salvaging these individuals--many who are men between the ages of 40 and 60, in the prime of their productive careers--would be a great saving to society. It's these people we're especially interested in. Many have a good functioning heart, but die from an electrical disturbance. If we can prevent this fatal arrhythmia from occurring, we can add many years to the lives of these people.

"At Stanford, we're using all three of these methods I've mentioned to study the problem of sudden cardiac death. This is one of our major areas of clinical research.

"These techniques have not been tested in enough patients to be able to scientifically establish their usefulness. However, clinical trials are going forward using each one. When statistical evidence is accumulated, it will be reported in the appropriate medical literature."

FOR IMMEDIATE RELEASE

STANFORD -- A patient at Stanford University Medical Center successfully transmitted his electrocardiogram 51,000 miles today (March 9), using only a small electronic device and an ordinary telephone.

The patient, 42-year-old Melvin Raymes, of Cupertino, Calif., relayed his electrocardiogram from Stanford to Manila in the Philippine Islands, then to a synchronous satellite over the Pacific, and then back to Stanford.

Dr. Donald C. Harrison, chief of cardiology at Stanford, and Dr. David S. Cannom, postdoctoral fellow in cardiology, received the transmitted electrocardiogram on another telephone in the same room, after it had travelled the 51,000 miles.

The experiment is part of an on-going evaluation by Stanford cardiologists of an instrument designed to help prevent sudden cardiac deaths. The device, which resembles a transistor radio, can monitor a patient's heartbeat during his daily routine, sound a warning in the event of abnormal cardiac rhythms which may be life-threatening, and transmit the patient's electrocardiogram (EKG) to his doctor from any location through an ordinary telephone.

Today's experiment, which marked the first known transmission of an EKG from a patient to his doctor, verified the capability of the device to relay electrocardiographic signals over long distances without distortion. A direct recording of the patient's EKG was made to check the accuracy of the transmitted signal.

"Today, we've demonstrated that this small electronic device can accurately transmit an electrocardiogram over long distances by phone," Dr. Harrison said following the experiment. "This is a very important characteristic of such a detection and warning system, since it allows the user to relay his EKG to his doctor from a remote location. It gives the patient the opportunity to consult with the physician and then take appropriate action.

"However, clinical trials to demonstrate the effectiveness of the device in detecting life-threatening arrhythmias and warning patients have not been completed or evaluated."

Harrison pointed out that the device is one of several methods which have been developed for monitoring patients as they go about their daily activities. "All of these techniques are now in the evaluation phase," he said.

As part of the evaluation process, clinical trials with a selected group of high-risk patients have been initiated at Stanford, he added.

Harrison emphasized that a public demonstration of one of these techniques was necessary to call attention to the "epidemic" of sudden cardiac death and the efforts being made to prevent it.

-more-

"Sudden cardiac death is one of the biggest health problems in the country right now," he said. "Of patients who have heart attacks each year in this country, approximately 150,000 die suddenly before they reach a hospital." In all, over 600,000 Americans die from heart disease per year.

The device used for today's 51,000 mile EKG transmission, known as the Ventricular Impulse Detector and Alarm (VIDA), has been developed by Cardiodynamics, Inc., of Dublin, California. It consists of a five-and-one-half ounce analog computer, attached to two skin electrodes which are applied to the patient's chest.

The patient's heartbeat is monitored continuously throughout his daily routine. The device sounds a warning beeper in the event of abnormal cardiac rhythms which may be life-threatening. At the onset of the warning, the patient can immediately transmit his EKG to his doctor from any location by holding a telephone receiver up to the device. He then acts according to his doctor's instructions.

The doctor can receive the call on an ordinary telephone, then press his receiver into a special terminal to obtain a printout of the EKG.

Cardiologists feel the device, if proven effective in detecting life-threatening arrhythmias and warning the user, will be especially valuable for heart patients who wish to travel or commute over long distances.

STANFORD -- President Nixon's message to Congress last week directing the Department of Health, Education and Welfare to develop "a safe and efficient" nationwide blood program represents a victory for Stanford University professor J. Garrott Allen of the School of Medicine.

Dr. Allen, a surgeon and international authority on hepatitis, has been a relentless critic of the present blood banking system as being unresponsive to the national demand for blood.

Among his targets have been the commercial blood banks because they often accept blood from derelicts, who may be the transmitters of such diseases as hepatitis, syphilis, and malaria.

Dr. Allen, whose studies have shown that the risk of hepatitis from paid donors is 11 to 70 times greater than blood from volunteers, began his campaign for a national volunteer program 17 years ago.

His pleas, however, for replacing the present patchwork system of blood banking fell on deaf ears among federal authorities. Even the prestigious National Research Council of the National Academy of Sciences, ignored the problem for many years, Dr. Allen said.

Only Leo Perlis, director of community services of the AFL-CIO, agreed with Dr. Allen. In 1971, the AFL-CIO endorsed the concept of an all-volunteer program.

Until 1969, Dr. Allen said, his campaign had been carried on primarily through articles in medical journals.

Disillusioned by the lack of results, Dr. Allen decided to bring his concerns to the attention of the public through the news media. Since the government didn't act, action had to be brought through a consumer revolt, he said.

"Then things began to happen," Dr. Allen recalled.

Congressmen and senators began to write him asking for advice on what an all-volunteer blood program should be. State legislatures introduced bills to regulate commercial blook banking. Response even came from the American Medical Association which, up to that time, had paid little attention to the blood problem, Dr. Allen said.

Among those who have contacted Dr. Allen are Representative Victor Veysey, Republican of California. His bill now pending in Congress would allocate $9 million to HEW in the first year to set up a structure for the supervision of blood collection, inspection services, and testing. Others were Sen. Charles Percy, Republican of Illinois, Sen. Vance Hartke, Democrat of Indiana, and Sen. Jennings Randolph, Democrat of West Virginia.

Last year, several newspapers carried exposés on the blood banking problems in their localities, Dr. Allen said. These included the New York Times, the Chicago Tribune, the National Observer, and Chronolog on the NBC Television Network.

-more-

March 9, 1972

On November 1, Dr. Allen said, after years in which his letters to the federal authorities went unanswered, he received a letter from Dr. Ian A. Mitchell, special assistant to the Assistant Secretary for Health Affairs at HEW. It said in part:

"We fully share your concern about the quality of blood for transfusions. The problem of hepatitis from blood transfusions is indeed a serious one." HEW now has a full-time staff working on the problem.

Informed of the President's message, which calls on HEW "to recommend to me as soon as possible a plan for developing a safe, fast and efficient nationwide blood collection and distribution system," Dr. Allen commented he is pleased.

He said this was only a beginning step. Development of an all-volunteer blood program would require participation of the field of medicine, blood banking, and the public. It would also require a nationwide public education program to encourage unpaid donors.

Dr. Allen said he fully supports a position paper adopted in February by the Red Cross, which now supplies up to 40 per cent of the national blood needs. Red Cross sources are 100 per cent volunteer. It sets the principles for such a program--volunteerism, blood availability to all free of charge, and free interchange of blood between blood banks.

Heart Transplant #41, Patient #40

STANFORD -- Stanford University Hospital surgeons performed a heart transplant operation Saturday morning (March 4) on a 48-year-old California man. He is reported to be in satisfactory condition.

The operation was performed by a team headed by Dr. Norman Shumway.

Hospital policy has been to withhold names of heart transplant patients if they so request. In this case, the recipient requested anonymity.

Including the new recipient, 14 of the 40 heart transplant patients operated on at Stanford are now living.

STANFORD -- Scientists have discovered a new class of regulatory genes believed to control specific immune responses of the body to antigens or foreign proteins like viruses and bacteria.

Ten of the regulatory genes were identified by researchers at Stanford and Harvard medical schools, and nearly 20 similar genes were found by other researchers during the past eight years.

This, however, is the first time that discovery of the genes and implication that they may influence predisposition of some people to common viral and bacterial infections has come to public attention.

Genes are units within chromosomes that transmit hereditary characteristics and also govern the development of cell structures.

Scientific interest in immune response genes has increased in recent months because of the growing number of associations between heredity and certain diseases being reported in medical journals and scientific meetings here and abroad.

These genes have, in fact, caused so much excitement in the scientific community that last week leading immunologists and geneticists met in La Jolla to partly pool their knowledge and to talk about development of the best methods for the laboratory experiments needed to confirm this type of link between heredity and disease.

The most exhaustive study of the immune response genes has been made by Dr. Baruj Benacerraf, professor of comparative pathology at Harvard Medical School, and Dr. Hugh O. McDevitt, associate professor of medicine and head of the immunology division at Stanford University School of Medicine. They discussed the long-term implications of the work in a special report in Science, a scientific journal.

In a series of experiments, the scientists injected animals with antigens. Animals which had one of the immune response genes could form a vigorous reaction against the corresponding antigen. This was marked by production of antibody and development of immunity.

Animals lacking such a gene would not become immune and were either totally or partially deficient in their antibody response to the antigen.

Immune response genes, called Ir genes, are believed to be linked to immune response cells which mature in the thymus. The scientists, however, do not know how these genes work. They believe the genes are somehow associated with the same immunological apparatus responsible for rejection of organ transplants.

And this is the intriguing part.

Recent findings suggest a relationship between rejection-triggering antigens in organ transplants and certain types of cancer and other disease, Dr. McDevitt explained in an interview. Among these are Hodgkin's disease, the rare rheumatic disorder systemic lupus erythematosus, and acute lymphocytic leukemia.

-more-

March 7, 1972

Exactly how the tissue rejection antigens, located on the surface of white blood cells, exert an effect on susceptibility to these diseases is unknown.

One possible mechanism, Dr. McDevitt pointed out, is that host antigens may provide a safe receptor site for the attachment of an invading virus. Still another possibility is that the virus "mimics" the biochemical characteristics of host antigens so that the animal cannot identify the invader as foreign and react against it.

A third possibility is that immune response genes located near the genes for transplantation antigens on the host chromosome affect the host's ability to react against antigens on an invading virus.

If a link between hereditary disease susceptibility and transplantation antigens is definitely established, scientists believe it could have great medical significance.

It could lead to development of tests for identifying those who are prone to certain diseases because of hereditary factors, Dr. McDevitt said.

He stressed the studies have dealt so far with mice and guinea pigs. Mapping is under way in laboratories in Maine, Michigan, Montana and Stanford to define the genetic relationship between specific immune response genes and tissue compatibility antigens. But the knowledge gained from animals could ultimately be applied in studies of the immune response of man, he said.

"There is evidence suggesting that specific genes may be one of several factors affecting susceptibility to cancer in both animals and man," Dr. McDevitt said. He cited these examples:

. Scientists have shown a genetic control of cell susceptibility to the Rous sarcoma virus which causes tumors in chickens.

. Another researcher has shown that a gene, closely associated with genes for tissue compatibility antigens, influences susceptibility of mice to a type of mouse leukemia.

. Working with former Stanford geneticist Walter F. Bodmer, now of Oxford University, Dr. McDevitt and his colleagues have identified a statistically significant association between systemic lupus erythematosus and tissue compatibility genes in man.

. Several laboratories in France, England and Australia have found a similar association between Hodgkin's disease and tissue compatibility genes in humans.

The Stanford immunologist believes studies should eventually be made to detect and type immune response genes in man. But this is not going to be simple.

In the course of their evolution, animals and man have developed a highly sophisticated, complex interplay of different forms of immune responses that simultaneously deal with a variety of needs, Dr. McDevitt commented.

To manipulate these responses, requires a much more precise understanding of how they occur, and what controls them than scientists now have.

Dr. McDevitt's work is sponsored by the National Institutes of Health, the Arthritis Foundation, and the American Cancer Society.

Editors and Science Writers: On March 9, at 4:00 p.m., cardiologists at Stanford University School of Medicine will conduct an experiment in which a patient's electrocardiogram will be transmitted over 51,000 miles, more than twice the circumference of the earth. To do this, the patient will utilize a pocket-sized electronic device and an ordinary telephone. The device, which also monitors heart activity and alerts the user to any irregularities in cardiac rhythm that may be life-threatening, is being evaluated by Stanford cardiologists. This experiment is designed to test whether the device can transmit an electrocardiogram over long distances free of distortion. It will mark the first transmission of an EKG by a patient to his doctor.

After the demonstration, Stanford cardiologists Dr. Donald C. Harrison and Dr. David S. Cannom will hold a press conference to discuss the significance of the experiment and possible future clinical applications of the device in preventing sudden cardiac deaths.

We regret the late starting time, but because of technical matters relating to the unique nature of the transmission, an earlier time could not be arranged.

You are invited to send your representatives to attend the experiment and press conference, which will take place in Room W001 at the Medical Center. Background details follow.

* * *

STANFORD -- Utilizing a pocket-sized electronic device and an ordinary telephone, a patient will attempt to transmit his electrocardiogram over 51,000 miles Thursday afternoon, March 9, at Stanford University Medical Center.

The experiment is part of an on-going evaluation by Stanford cardiologists of an instrument designed to help prevent sudden cardiac deaths.

The five-and-one-half ounce device can continually monitor a patient's hearbeat during work or any other activity, sound a warning in the event of irregular cardiac rhythms which may be life-threatening, and transmit the patient's electrocardiogram (EKG) to his doctor from any location through an ordinary telephone.

Known as the Ventricular Impulse Detector and Alarm (VIDA), it has been developed by Cardiodynamics, Inc., of Dublin, California.

Thursday's 51,000 mile transmission is designed to test the capability of the device to relay an electrocardiogram over long distances without distortion. The patient will attempt to transmit his EKG to Manila in the Philippine Islands, then to a synchronous satellite over the Pacific, and then back to Stanford. A direct recording of an EKG will be made to verify the accuracy of the transmitted signal.

As part of the evaluation process, clinical trials of the device with in-hospital patients have begun at Stanford. Outpatient trials using a selected group of high-risk patients who have experienced a heart attack or abnormal rhythms will soon be initiated, said Dr. David S. Cannom, postdoctoral fellow in cardiology.

Stanford cardiologists believe that this type of coronary detection and warning system, with provision for physician review of the patient's EKG from a remote location, may help prevent sudden cardiac deaths and significantly reduce the number of office visits for many heart patients.

-more-

March 6, 1972

EKG Transmission to Philippines
222

"Sudden death is frequently the initial manifestation of coronary heart disease," said Dr. Donald C. Harrison, chief of cardiology at the Medical Center. "However, many patients have electrocardiographic changes of abnormal rhythms prior to the fatal arrhythmia resulting in sudden death.

"If such abnormalities in cardiac rhythm are detected, the prophylactic administration of anti-arrhythmic drugs may reduce the incidence of sudden death."

The device consists of a pocket analog computer, resembling a transistor radio, attached to two skin electrodes which are applied to the patient's chest. The patient's heartbeat is monitored continuously throughout his daily routine. The device sounds a warning beeper in the event of abnormal cardiac activity which may be life-threatening. This warning is based on specific danger criteria established by the patient's doctor. At the onset of the warning, the patient can immediately transmit his EKG to his doctor from any location by holding a telephone receiver up to the device. He then acts according to his doctor's instructions.

The doctor can receive the call on an ordinary telephone, then press his receiver into a special terminal to obtain a printout of the EKG.

Cardiologists feel the device may be especially valuable for heart patients who wish to travel or commute over long distances.

Heart disease is the leading cause of death in the United States and kills over 600,000 Americans per year.

STANFORD--A committee to review the programs of the Stanford University School of Nursing and recommend future objectives has been appointed by Dean Clayton Rich of the School of Medicine.

Dr. Rich called on the committee to "develop an effective and intellectually stimulating educational program," and to give its task high priority. The study will be funded by a grant from the San Francisco Foundation.

The dean outlined these areas for committee consideration:

. The possible development of a program to prepare nurse practitioners. (As presently defined by nursing standards such a nurse is trained to give primary care to families as a whole and to aid physicians in providing for family care in areas where it is not available).

. Use of the resources of the Stanford faculty at large in training of nurses rather than predominant use of a separate faculty of nursing educators. A program for nurse practitioners would draw on many fields--biology, human behavior, nursing arts, and diagnosis and treatment. The program would lead to a baccalaureate degree after four years, and a master of arts degree a year later.

Dr. Rich urged the committee to review the role professional nurses of the Stanford Hospital should play in nursing education. He said Hospital nurses may be under-utilized in this area.

He also said: "The training of nurse practitioners might include instruction in diagnosis and management which has many similarities to the training of a physician. I would expect that Medical School faculty could make a significant contribution to this phase of nursing education."

Last month Dr. Rich announced that a proposal by two nursing educators to create an autonomous graduate school of nursing could not be implemented for financial reasons. But the dean accepted many of their recommendations which he felt were "feasible and desirable."

"Practical considerations dictate that students of nursing at Stanford be able to utilize the resources of the University to the fullest extent possible," he said.

Meanwhile, the School of Nursing has announced that it will not admit students to the present five-year program next fall until the committee makes its proposals and a new curriculum is developed.

The committee is chaired by Susan Brueckner, an alumna of the School of Nursing and nursing project director at Stanford Hospital. Members include Linda Cronenwett, instructor in the School of Nursing; Ludmila Davis, director of operating rooms at Stanford Hospital; Dr. Michael Dennis, director, physicians assistant program; Dr. Count D. Gibson, professor and chairman, Department of Community and Preventive Medicine; Sue Loper, nursing student; Grace E. Ringressy, professor and director, School of Nursing; W. Richard Scott, professor of sociology; Barbara Shonk, representative, Stanford Nurses Club; Florence Stroud, instructor in nursing, University of California School of Nursing; Paula Tognetti, nursing student; and Steven M. Zifferblat, assistant professor, School of Education.

STANFORD -- A new method to probe accurately the interior of the nucleus of living human lymphocytes (white cells) has been developed by a Stanford University medical researcher.

Lymphocytes are the cells which provide immunity against human tumors and transplants.

"The nucleus is especially important in controlling such lymphocyte activity," said Dr. John H. Frenster of the Department of Medicine. His work was supported by a grant from the National Cancer Institute.

The new method, developed by Dr. Frenster, employs a chemical that interacts with the genetic material (DNA) in cells. This interaction can be visualized with great accuracy by electron microscopy.

"Previously, no electron microscopy was available for such studies," Dr. Frenster explained.

He said the new method has revealed the control points for lymphocyte activity to be highly localized to the central area of the cell nucleus.

"By a better understanding of these control points, we may be able to increase lymphocyte activity against cancer cells or to decrease lymphocyte activity against transplants in patients," Dr. Frenster explained.

The Stanford scientist's work was reported in the current issue of Nature, an international scientific journal.

STANFORD --

A Stanford University scientist Thursday, April 20, urged that all national biomedical control activities be placed under a single director in an independent Consumer Safety Agency.

Dr. Leonard Hayflick said the Food and Drug Administration (FDA), the Division of Biologics Standards (DBS), and the comparable control activities of the Department of Agriculture and the Center for Disease Control should be combined.

"Many of the activities of these agencies and others now overlap," he said. "Because they require equivalent kinds of scientific expertise and laboratory facilities, they represent a wasteful duplication of effort.

"The distinction between those products that should be controlled by the FDA and those controlled by the DBS is becoming less discernible."

Hayflick, a professor of medical microbiology at the Stanford University School of Medicine, made his proposal in testimony before the U.S. Senate Subcommittee on Executive Reorganization in Washington, D.C. The subcommittee is chaired by Sen. Abraham Ribicoff (D-Conn.).

At present, according to Senator Ribicoff, several agencies are responsible for protecting the public against dangerous foods and drugs.

FDA tests drugs to see that they are effective. Vaccines, the primary means of preventing epidemics, are drugs, but these are tested by the DBS. The confusion is increased by the fact that vaccines for animals used for food are tested neither by the FDA nor the DBS, but by the Department of Agriculture.

This gray area, Hayflick suggested, could be covered simply and more efficiently by "an amalgamation of not only these agencies, but all federal agencies responsible for the public health."

Hayflick said his recommendations were based on personal experience in dealing with the policies "and some of the people" at DBS. In 1961, Hayflick developed a human cell strain that was found to be free of unwanted viruses. The strain was considered ideal for vaccine production because it lessened the likelihood of contamination from viruses found in monkey kidney and duck eggs where vaccines are made.

Because of their safety, Hayflick's cells have been used in many countries to make vaccines, and by the U.S. Armed Forces. Yet the first human cell vaccine production for civilian use in the U.S. was licensed by the DBS only last month.

"DBS has been inordinately slow to respond to new research developments which lead to improvements in the safety, purity, and efficacy of virus vaccine products," he said.

Hayflick also said the DBS involved itself in a serious case of conflict of interest in 1969. The agency licensed a rubella (German measles) vaccine developed by its own scientists and discouraged production of similar vaccines developed by independent scientists.

"It now appears that the DBS rubella strain produces more undesirable side effects in recipients than do the other strains," he said. "It is very likely that the next few years will see a shift in use from the DBS rubella strain to one of the earlier unsuccessful candidates."

Hayflick added that "no control authority should be permitted to sit in judgment of products when the choice is between substances developed by that control authority and those competing with it from other laboratories."

STANFORD -- At age three Amy had not yet begun to talk. Her parents thought she might be retarded. Without treatment, she might have been unable to enter a regular class at school.

The initial workup by language specialists showed that Amy was above average in intelligence. A speech therapist worked with her individually to stimulate her, and later she was put in a group. After a year and a half of therapy, she was speaking and learning normally. By the end of second grade, Amy was a superior student.

Carl had suffered a stroke and could not communicate. When he came to the language clinic, he had not spoken for three years. With speech therapy, Carl talked almost normally. Now married, he is a volunteer who helps lead sessions for other patients.

These two patients are typical cases of the Stanford Speech and Language Clinic. With professional help, they have rejoined society.

Last year the fate of the clinic's future was uncertain. The Stanford School of Medicine had considered discontinuing it for financial reasons. Speech rehabilitation requires time. It can never be solely supported by patient fees. The problem facing Stanford also affected other language programs in the community.

To continue valuable speech services, Stanford joined forces with two other local institutions to eliminate costly duplication. They were the Palo Alto Medical Clinic and Children's Hospital at Stanford.

The three have formed the Stanford Center for Communications Disorders, which opened last September in a building at Children's Hospital. The facility is headed by Dr. Kathryn Beadle, a speech and language pathologist. It may serve as a model of coordinated diagnosis and treatment for other institutions throughout the country, according to Dr. Beadle.

A staff of six therapists and Dr. Beadle manage communications disabilities in all age groups. Problems include language development difficulties of children, voice disorders of adults and speech dysfunctions associated with stroke.

Children under two are rarely seen at the center, simply because faulty speech development at an early age is difficult to recognize, Dr. Beadle pointed out. Language development studies over the past ten years, however, have given specialists norms to go by for guides. "The younger a child is when we first see him or her, the better," Dr. Beadle noted.

Patients under three have usually been referred by an audiologist who has determined that suspected speech problems are not related to any hearing deficiency. The majority of children treated at the center are between three and five. By the time these patients are old enough for school, they no longer need special help, or they can be treated by the school therapist. Only school children with severe speech problems are seen by center personnel.

-more-

Language difficulties of many youngsters are related to neurological immaturity, technically called minimal cerebral dysfunction. This involves underdeveloped perception and motor control. Children with this disorder cannot focus their attention or concentrate well, and have difficulty seeing or understanding things as they should. Therapy for such patients is therefore directed at increasing attention and perceptual skills as well as building language.

Much of the child therapy at the center is done in groups. Dr. Beadle feels that group participation should generally be a part of any child's treatment.

"The group is exciting and gives the patient more motivation. It is also helpful as a transition to the schoolroom," she said. "In addition, therapy activities for certain problems, such as the perceptual difficulties, are particularly suited to group work."

Adult problems are primarily voice disorders and strokes. Voice disorders concern speaking improperly. Misusing the voice, for example, can cause swelling and sometimes, growths on the vocal cords which interfere with speech. Such patients are referred to the communications center by the Medical Center's Ear, Nose and Throat Clinic or by other otolaryngologists in the area. Therapy retrains these patients to use their voices properly in order to eliminate the underlying causes of pathology.

Many of the adult patients are stroke victims who have lost the ability to speak or to understand speech. When treated soon after an attack, many of these patients who might otherwise remain severely handicapped, regain their power to communicate.

Most adult therapy is individual, but group work is done when a group situation is advantageous. At present the center has two groups for stroke patients, one for adult stutterers, and another for adolescent stutterers. There are also groups for parents of children with speech disabilities, since any successful therapy for a child requires cooperation of the parents.

In addition to diagnosing and treating individual patients, the center works closely with communities throughout the Bay Area to evaluate school children with learning difficulties. Staff do not necessarily do therapy with these children, but they make recommendations for the type of class or teaching a child may require. If treatment is needed, but Stanford is too far away for the patient, the center helps make arrangements for therapy in the patient's local community.

Stanford's communications center is also an integral part of other research and treatment programs in the area. With the Whitcomb Convalescent Hospital in Menlo Park, it participates in a co-care program for stroke patients, which insures that the extended care services patients need after they leave the hospital are available to them in the community.

Therapists are consultants to the Morgan Center in Palo Alto for emotionally disturbed children, and the Crippled Children's Services, which refer children with speech-related disabilities. Center personnel also work with various departments of the Stanford University and Children's Hospitals, and with the Stanford Birth Defects Panel.

Stanford Hospital is providing funds for the center's first three years of life. Dr. Beadle hopes that in the future the center will attract federal and private support. Outside financial support is necessary because patient fees do not cover the cost of operating the center.

"If we charged patients enough to pay for all the center's costs, most of them could not afford our services," Dr. Beadle said. "Our main purpose is to serve the community, and if the center's patient waiting list is any indication, speech services are certainly needed in this area."

HEART TRANSPLANT PATIENT #42 April 9, 1972

STANFORD -- A 45-year-old California man became the 42nd heart transplant recipient at Stanford University Hospital Sunday afternoon (April 9). He is listed in satisfactory condition.

The operation was performed by a team of surgeons headed by Dr. Norman Shumway.

Hospital policy has been to withhold names of heart transplant patients if they so request. In this case, the patient requested anonymity. .

Including the new recipient, 16 of the 42 heart transplant patients operated on at Stanford are now living.

Since infants have not yet developed the ability to ward off cold and maintain a stable body temperature, they must be transported in a neutral thermal environment. The Stanford infant transporter provides a comfortable temperature for the infant through the use of radiant heat warmers, a principle adapted from the Apollo space program.

The transporter has an oxygen ventilation system that will supply two to three hours of oxygen, battery powered monitors for heart rate; fluid intake, blood pressure and temperature; portable rechargeable battery units for the systems, and a stabilizing unit to prevent injury to the infant during sudden changes in speed or altitude. These features are still being streamlined and improved, according to Hackel.

A team composed of Drs. Hackel, Sunshine, and Johnson plus Drs. Nancy Edwards and Arnold Goldstein, fellows in newborn care, is responsible for coordinating transfers. One member of the team is always available.

When the Stanford nurseries are called to admit an infant, the appropriate means of transportation is determined. If the patient will be brought to Stanford by helicopter or airplane, the transport coordinator on call is notified to make the necessary arrangements. The coordinator, a pediatric house officer and a medical student, take the equipment in an ambulance to the heliport where they board the helicopter to fetch the infant.

At the outlying hospital the infant is transferred from the nursery to the Stanford transport unit and any necessary treatment is begun. During the return trip, the coordinator radios the Medical Center to inform the nursery of the patient's condition and to alert the ambulance for the expected arrival at the heliport.

As soon as the helicopter lands, the infant in the transporter is taken by ambulance to the nursery. There the infant is transferred to a hospital incubator where full intensive care gets underway.

Although air transportation for newborns is not a new idea in this country, it has not been used to a great extent in California. "We expect to expand the role of Stanford as a regional medical care center through development of an integrated transport service and we hope it can be used as a model for other hospitals in the state," said Hackel.

The heliport, partially funded by the Jr. Women's Club of Palo Alto, meets the requirements of the Federal Aviation Administration and the California Board of Aeronautics. It is equipped with floodlights to illuminate the landing area at night, and a telephone for on-the-spot communication.

Editors: Photos available upon request if not included with release.

The life-saving drama of transferring critically ill newborn infants to the intensive care nurseries at Stanford University Hospital is often played in the sky.

A heliport completed last April to provide a convenient landing pad near the Medical Center for helicopters, has enabled babies in critical condition to be transported to Stanford from distant hospitals in record time. So far 20 mercy missions for tiny infants have been flown by helicopters using the heliport, which is located 700 feet from the emergency room entrance.

The helicopter service is part of an interhospital transport system for rapid transfer of newborns designed and managed by Drs. Philip Sunshine, Alvin Hackel, and John Johnson of the Departments of Pediatrics and Anesthesia.

Stanford's newborn intensive care units serve area III of the California Regional Medical Programs, but acutely ill infants are brought from hospitals throughout central California or western Nevada which do not have the facilities to treat them. Close to 200 babies are transferred to Stanford each year to be placed in the intensive care nurseries, or the Premature Research Center, where intensive care is subsidized under terms of a grant to Stanford from the National Institutes of Health. Most of these babies are less than 24 hours old, and they usually have breathing difficulties or require major surgery.

"The most crucial period for the infant is the time it takes Stanford pediatricians to reach the baby, for once they are by the infant's side, they can initiate preliminary treatment and then continue to provide emergency care en route," explained Hackel.

"The transfer between hospitals should be as quick as possible since complete intensive care is not possible until the baby is at Stanford. The ideal traveling time between hospitals is less than one hour," Hackel said.

Most of the infant transfers come from within a 30-mile radius, and for these surface ambulance is used. Transfers beyond 30 miles are done by helicopter or airplane, weather permitting. Helicopters chartered from an Oakland firm are used for interhospital distances up to 100 miles and airplanes make transfers from hospitals more than 100 miles away. The longest trip the Stanford infant transport team has made yet was to Cedarville, 380 miles north of Stanford.

For air transport, special lightweight equipment had to be designed. The Premature Research Center worked with the Department of Anesthesia and the Thermosciences Division of the University's Department of Mechanical Engineering to modify and adapt the basic neonatal transport unit for use in helicopters and airplanes. The project was headed by Robert Moffat, associate professor of mechanical engineering.

STANFORD -- American schools must dramatically improve the learning environment they provide for children and help promote family strength, Stanford University child psychologist Dr. Alberta Siegel said Thursday (April 6).

Dr. Siegel said that our schools hold the key to how well individuals will meet the requirements of the 21st century and adapt to changing roles for men and women.

"Females and males will be more likely to be alive and well in century 21 if our schools reform all aspects of the learning environment they provide for children, and if they modify all their practices to bring them into line with the continuing viability and strength of the family," she said.

Dr. Siegel, a member of the Surgeon General's Committee to study the effects of television violence on children, made her remarks at the annual meeting of the American Educational Research Association in Chicago.

Emphasizing the significance of a child's early learning, she said, "We must recognize that the most important learning occurs within the family, from the people with whom the child has strong emotional bonds."

Because of this, she continued, it is vital for other social institutions to aid children by aiding the family. Schools, as "social institutions which can aid the family or contribute to its further deterioration," must be in the forefront of this movement, she said.

Dr. Siegel listed five suggestions for American schools. They included:

-- implementing employment practices which reduce pressures on employees to make geographical moves to advance their careers. Such frequent relocation, Dr. Siegel said, can be destructive to family life.

-- creating more part-time positions for women so they could more easily hold jobs and also adequately fulfill their responsibilities as wives and mothers.

-- avoiding sex-role stereotyping in all employment fields.

-- minimizing the barriers to the employment of spouses by making it easier for husband and wife teams to work together at the same institution.

-- encouraging more students to consider careers in the health professions, and providing better health care insurance for all employees.

By following such suggestions, Dr. Siegel said, schools could become models for other social institutions and help eliminate the "pollution of the family" caused by geographical dispersal, industrialization, electronic communication, and other technological advances.

STANFORD -- If the walls of the ivory-tower medical school have not come tumbling down, they at least have been breached. The latest sign of this comes from the Stanford University School of Medicine whose students now influence decisions on the very issues that affect their education.

In the last two years, students have gained representation on most of the important committees responsible for Medical School policies. These range from academic matters to the extent and quality of health care delivery.

"We are considered partners with faculty and administration in working to rectify many of the shortcomings of medical education at Stanford," said Tom Raffin, co-president of the Stanford Medical Student Association (SMSA).

Dean Clayton Rich said students have become more interested in the Medical School as an institution, are more vocal and forceful, and want access to the decision-making process, particularly in the area of curriculum.

"My observation is that students have made very important contributions because in general they have very accurate perceptions of the quality of the educational process in which they are involved," the dean added.

Student participation on committees is a by-product of the movement for educational reform of the mid-1960's. Stanford medical students began looking at their own educational environment, and saw certain aspects they wanted changed.

They saw, for instance, that Stanford emphasized medical research and training of specialists. Stanford's highly specialized facilities attracted mostly patients with rare and exotic diseases, virtually to the exclusion of routine cases which are needed for training young M.D.'s.

"In fact, the undergraduate educational program had become a diffuse, poorly controlled experience which simply reflected, in terms of quality, its low priority," Raffin said.

(While it is true that by the standard of the size of the undergraduate class, Stanford has put less emphasis in that area, it was not done by design. Nobel Laureate Joshua Lederberg says there has never been a federal mandate for support of undergraduate medical education, and medical schools have been able to bootleg a great deal of support for it as a by-product of research funding. The growth of the specialties occurred for two reasons, Lederberg adds. One is the kind of facilities they are able to provide, and the other has to do with the character of the patient population served by Stanford which requires highly specialized care.)

Nevertheless, the medical students wanted change, and they felt they could effectively bring it about if they had a say.

As a result, students have been given unprecedented voice in considering new faculty and tenured appointments. Two students served on the search committee which last September chose Dr. Rich as dean of the Medical School. -more-

Other students are currently aiding in the search for new chairmen in pediatrics, medicine, anatomy and radiology. They are also represented on committees dealing with curriculum development, admissions, patient care, primary care, financial aid, and the deliberations of the Medical School's faculty senate.

The SMSA, according to Raffin and co-president Maida Taylor, would like to see students even more involved in the selection of faculty at the Medical School. The organization is working with a dean's committee to set up means for using student evaluations in tenured appointments and promotions.

The students have not yet gained the privilege of serving on the executive committee, the highest level policy-making group composed of department chairmen of the Medical School.

"Unfortunately," said Raffin, "the voting majority of the committee does not think the SMSA should send an observer to the meetings, but we hope to discuss further such a proposal with them."

Miss Taylor and Raffin feel it is important for Stanford students to be active in national and community medical affairs not only for the educational benefit, but to help make constructive changes in the national health care system. At the local level, SMSA has a representative on the governing council of the Santa Clara County Medical Society, and students take part in some of its standing committees.

Looking into the future, Miss Taylor and Raffin believe that while Stanford should maintain its strength in basic and clinical research, it cannot continue to focus most of its attention in these two areas alone.

"At present, the Medical School is not completely meeting its responsibilities to health students or the community," Miss Taylor and Raffin said. "The program does not satisfy the needs of today's medical students, and the academic distance that Stanford has maintained from the community will keep it out of evolving health care delivery systems in this area."

Stanford is finally beginning to think about an active role with health care consumers and physicians in the community, the student leaders said.

At present, discussions are under way with other area institutions to determine how Stanford can make use of their medical facilities for teaching. Already, the Medical School has signed a formal agreement with Santa Clara Valley Medical Center to bring more medical students to the Center for first-hand instruction from hospital staff and Stanford faculty members.

"Discussions now under way with the Palo Alto Medical Clinic and other area facilities," continued the SMSA co-presidents, "will be crucial not only to a well-organized and integrated health care delivery system, but to the survival of the Stanford Medical School.

"Without deliberate and well planned steps in the immediate future, we will have failed to move ahead at a most opportune time, and it is possible that a second chance may not be forthcoming."

STANFORD -- Dr. Charles E. McLennan, professor and chairman of the Department of Gynecology and Obstetrics at Stanford University School of Medicine for the past 25 years, will relinquish his chairmanship responsibilities at the end of the year.

He has requested to be relieved of administrative duties by December 31, 1972 at the latest, to devote time to teaching, research and clinical care. Dean Clayton Rich has appointed a search committee to choose a successor.

Dr. McLennan is author of a textbook, Synopsis of Obstetrics, and numerous scientific publications. A member of several professional societies, he is a director of the American Board of Obstetrics and Gynecology, vice president of the American Gynecological Society, president-elect of the Pacific Coast Obstetrical and Gynecological Society, and a past president of the Society for Gynecological Investigation.

Prior to joining the Stanford faculty in 1947, Dr. McLennan was chairman of the Obstetrics and Gynecology Department at the University of Utah. He also served on the faculty of the University of Minnesota where he earned his M.D. degree in 1934 and his Ph.D. in 1942.

STANFORD -- Dr. Windsor Cooper Cutting, former dean of the Stanford University School of Medicine, died Monday morning (May 29) in his home in Hawaii. Cause of death is undetermined at the present time.

Dr. Cutting, 64, also served as dean of the School of Medicine at the University of Hawaii from its establishment in 1965 until July of 1971. He remained on the faculty as professor of pharmacology, and was due to retire from the University at the end of the current academic year.

A 1932 graduate of Stanford Medical School, he joined the Stanford faculty in 1938 following fellowships at the Courtauld Institute of Biochemistry in London and at Johns Hopkins University. He became a full professor in 1946, and was appointed executive head of the Department of Pharmacology and Therapeutics four years later.

Dr. Cutting was named dean of the School of Medicine in 1953, by President Wallace Sterling. He served in that position for four years before he resigned in 1957 and was appointed professor of experimental therapeutics.

In 1964, after 26 years at Stanford, Dr. Cutting was appointed the first director of the Pacific Biomedical Research Center at the University of Hawaii. A year later, he became the first dean of the School of Medicine at Hawaii.

An expert in the study of antibiotics and virology, he authored over 200 medical papers and one book, Handbook of Pharmacology: The Actions and Uses of Drugs.

Dr. Cutting willed his body to the University of Hawaii Medical School. Contributions will be used to support a memorial lectureship in his name.

He is survived by his wife, Mary, three sons and three daughters.

STANFORD--Dr. Thomas A. Stamey, professor of surgery and head of the division of urology at Stanford University School of Medicine yesterday (May 24) was awarded the American Urological Association's (AUA) annual Hugh Hampton Young Award for his work on the diagnosis and treatment of urinary tract infections.

The presentation was made at the annual meeting of the AUA in Washington, D.C., by Dr. W.E. Kittredge, president-elect of the Association.

"Dr. Stamey's research in dealing with the vital functions of the kidneys and urological medicine has been invaluable to the medical community," Dr. Kittredge said.

A 1948 graduate of Vanderbilt University, Dr. Stamey received his M.D. from Johns Hopkins University School of Medicine in 1952. He served on the faculty at Johns Hopkins and was chief of urology at Baltimore City Hospital for three years prior to his appointment as associate professor of surgery at Stanford in 1961. He was appointed to his present position in 1964.

Dr. Stamey is the editor of Urology Digest, and a member of the editorial board of two other medical journals. He is the author of two books--Renovascular Hypertension, dealing with the methods of studying kidney conditions in man which lead to high blood pressure, and Urinary Infections, now in press. He has also published numerous papers on kidney physiology, urinary tract infections, and hypertension.

Recently appointed a member of the scientific advisory board of the National Kidney Foundation, he is also a diplomate of the American Board of Urology.

The Hugh Hampton Young Award, which consists of a gold plaque and $2000, honors the late physician and educator who was clinical professor of urology at Johns Hopkins School of Medicine for 48 years. He also served as director of Brady Urological Institute, was co-author of the definitive two-volume work, "Young's Practice of Urology," and founder of the Journal of Urology.

STANFORD -- A Stanford University surgeon today (May 24) urged reconsideration of heart transplantation as "appropriate therapy" for terminally ill heart patients.

"We believe significant progress has been made since 1967, both specifically in heart transplants in terms of selection, treatment and survival, and in the results of organ transplantation generally," said Dr. Eugene Dong, Jr., associate professor of cardiovascular surgery and a member of the heart transplant team at Stanford Medical Center.

"The past reveals that cardiac transplantation has resulted in a group of pain free, mobile, socially and vocationally rehabilitated patients, selected by current technology from a group of terminally ill patients," he said.

Dong made his remarks before an international symposium on clinical organ transplantation in Richmond, Virginia. Co-authors of the report were Dr. Norman E. Shumway, professor of cardiovascular surgery and a pioneer in heart transplantation, and Drs. Randall B. Griepp and Edward B. Stinson, two other members of the Stanford surgical team.

Forty-three patients have received heart transplants at Stanford since the program was initiated four-and-a-half years ago. Sixteen are presently surviving.

"If a patient survives the first three months after transplantation--and 22 patients have--75 per cent will survive to one year, 67 per cent to two years, and 27 per cent to three years," Dong said.

He attributed the rapid decline between the second and third years to poor survival statistics during the first year of the program. He noted that in the first year of the program (1968), 22 per cent of the patients survived one year, whereas 50 per cent of those receiving transplants in 1970 and through May of 1971 have survived at least one year.

Citing these statistics, Dong contended that "cardiac transplantation should be reconsidered as appropriate therapy for advanced heart failure due to irreparable myocardial disease using the proper selection criteria."

Experience at Stanford has shown that the operation can have a low surgical mortality and can bring about prompt and uniform improvement in cardiovascular function, he said.

The critical period for a heart transplant patient is three months following surgery, during which cardiac rejection crises are most likely to occur. After this, Dong said, "there is the appearance of a period of graft acceptance which is just as real for heart grafts as for kidney grafts."

But he emphasized that the most significant consequence of the program has been to return many patients to an active life, including virtually all of the current surviving patients and several who died over 18 months after receiving transplants.

-more-

"Most important is the physical, social and vocational rehabilitation achieved by the group as a whole, irrespective of the improved cardiovascular status," he said.

Dong contrasted the survival statistics of the heart transplant recipients at Stanford with those of patients who were selected for transplantation but could not be operated on for a variety of reasons. Average survival for these 20 patients was 30 days. Half died by the 10th day after selection, and only one lived longer than 95 days.

He attributed the improvement in the Stanford program to several factors, including better patient selection, improved recognition of rejection, more effective immunosuppressive drugs, and more aggressive diagnostic efforts against infection.

On the subject of mechanical hearts, Dong said, "Despite significant and widespread interest in mechanical devices, design factors for control, power, and biocompatible materials, costs of production for energy sources, and reliability make the issue of a total replacement device real only on a time-scale of a decade, if indeed that soon.

"On the other hand," he continued, "heart transplantation is available now, and the need for its wider and appropriate application is urgent."

The first human heart transplant at Stanford was performed in January of 1968. Nine years earlier, in 1959, Dr. Shumway and Dr. Richard Lower (now at the Medical College of Virginia) announced perfection of the surgical technique developed in animal research which is the basic technique used in human heart transplantation today.

Since 1959, Drs. Dong and Shumway have studied the immunologic problem of cardiac rejection and methods of recognizing and treating it.

Stanford's longest surviving heart transplant patient is Carl Sheaffer, a retired plumber from Winchester Bay, Oregon. Sheaffer received his new heart on October 26, 1968, and is the fourth longest surviving heart transplant patient in the world.

STANFORD -- Students and faculty members at Stanford University School of Medicine no longer have to spend hours poring through lengthy indexes and journals to find references concerning a particular medical subject.

With a new computer storage and retrieval system called MEDLINE (MEDical literature analysis and retrieval system on LINE), they can now complete a thorough search in a matter of minutes.

"A search on a very specific topic which would otherwise be very time-consuming or perhaps impossible can be performed in just a few minutes with this system," said Peter Stangl, director of the Medical School's Lane Library.

The Medical School became licensed to use MEDLINE in January, Stangl said. After several weeks of testing, searches began in March.

The data base for the system is housed in a central computer in the National Library of Medicine in Bethesda, Maryland. It includes almost 420,000 titles from 1,100 medical journals dating back to January 1, 1969.

The computer can presently accommodate about 500,000 titles, or up to four years of publications, Stangl said. Throughout this year, new titles will be collected and fed into the computer. At the end of the year, 1969 entries will be dropped, making room for 1973 to be added.

Stanford is one of six authorized MEDLINE users in California, and 70 in the United States. Each of the California installations serves a designated area in the state. Stanford will support Area III of the state's Regional Medical Programs, which includes 11 counties in mid-California.

Eventually, it is projected that about 200 medical schools, libraries, and hospitals will be using the system, Stangl said. The computer is capable of responding to 47 or 48 simultaneous users without a delay of more than 10 seconds, he noted.

Access to the system is by a communications network linking the authorized MEDLINE users with the main computer in Bethesda. The hookup is established via a local telephone call, Stangl said.

-more-

Searches are performed at Stanford at a small computer terminal in Lane Library operated by Paul Hanson, reference librarian. Hanson responds to a series of question prompts at the terminal on the basis of information provided him by the researcher requesting the search.

Each reference in the system contains title, author, source, date published, language, and those subject headings assigned to it by the National Library of Medicine's indexers. A reference can be retrieved by including in the search statement any combination of the various data elements given above, Stangl said.

"For example," he noted, "the search statement, 'vision disorders and children, and English, and 1971 thru 1972,' would retrieve all recent articles in English dealing with pediatric vision disorders."

MEDLINE evolved from two earlier computer systems for searching medical literature, Stangl said.

The earliest, MEDLARS (MEDical Literature Analysis and Retrieval System), was established in 1963. It includes all 2,400 medical journals found in Index Medicus, the complete bibliography for the health services. But MEDLARS conducts 15 to 50 searches together in a "batch" system, and requires from two to six weeks to provide responses, Stangl said.

In an effort to make the data available on a more immediate basis, an on-line computer system called AIM-TWX (Abridged Index Medicus-TeletypeWriter eXchange) was designed in 1969. However, this system includes only about 120 medical titles, an insufficient number for many medical schools and libraries, Stangl said. Also, AIM-TWX is operated on straight long-distance telephone charges, making the expense prohibitive for many users.

The development of the MEDLINE system was supported by the Lister Hill Center for Biomedical Communications at the National Library of Medicine.

Health professionals interested in using the installation at Stanford should contact Lane Library. At the present time, all searches are conducted free of charge.

STANFORD -- James G. Moore, director of personnel services at St. Mary's Hospital and Medical Center in San Francisco, has been appointed director of personnel at Stanford University Hospital.

The appointment, which becomes effective June 5, was announced today (May 15) by Dr. Thomas A. Gonda, director of Stanford Hospital.

Moore, 39, is a 1958 graduate of the University of Washington. He also did graduate work at Gonzaga University.

He was appointed to his current position at St. Mary's in June of last year. Prior to that, served as personnel director at Sacred Heart Medical Center in Spokane, Washington for 11 years.

Moore replaces Kenneth Dunkle, who resigned in March to become personnel director at Mt. Zion Hospital in San Francisco. In the interim, assistant personnel director William Hoffman has served as acting director of personnel.

STANFORD -- An infectious duck disease never before reported on the West Coast is responsible for the deaths of ducks and swans at the Palace of Fine Arts lagoon in San Francisco, according to Stanford Medical School veterinarians.

Their deaths most likely resulted from duck virus enteritis, a highly contagious, usually fatal disease caused by herpes-type virus that infects ducks, geese and swans. The ducks infected were Muscovy ducks, a domestic breed, and the disease is potentially most damaging for commercial duck breeders, said the investigators.

Five ducks and a swan were sent to Stanford by Palace of Fine Arts officials when they were found dead two weeks ago. Veterinarians Bret Snyder and Jim Fox analyzed lesions from the birds and then reported their findings to a U.S. Agricultural Department official in Southern California, who confirmed the disease. Although the investigators were 99 per cent sure of their diagnosis, they sent specimens to an East Coast laboratory for federal verification. Several more Muscovy ducks have since died, in addition to other breeds of waterfowl.

The disease was first reported in this country in 1967 in New York where it has since caused extensive damage in domestic ducks. Other cases have occurred in Pennsylvania and Maryland, but this is the first time the duck virus has been reported in this area, noted Snyder.

"It is possible that the disease was brought to the San Francisco area by wild birds who migrated over the Palace of Fine Arts. It is likely that it has been in this state for a little while and that the Palace ducks are not the first case," said Snyder.

The infection does the most damage to domestic ducks who live in closer quarters, explains Snyder. There is no cure for the disease, he added, but there is a vaccine for its prevention, although it has so far only been licensed in New York.

Once the federal authorities have verified the virus they will decide what measures to take. Snyder felt that the vaccine for protection will probably be licensed for use in California.

He added that if the disease becomes widespread, measures taken might be similar to those now in effect for an epidemic of Newcastle's disease in Southern California chickens. There the birds are quarantined to stop movement of the disease, and infected flocks are exterminated.

STANFORD--Dr. Sol Spiegelman, one of the nation's leading cancer researchers, will deliver the first Edwin W. Schultz Memorial Lecture Wednesday, May 17, at Stanford University School of Medicine.

His talk, entitled "Human Cancer and the RNA Tumor Viruses," will begin at 4:15 p.m. in Room M106 at the Medical School.

Dr. Spiegelman, recently appointed to the President's National Cancer Advisory Board, is director of the Institute of Cancer Research and professor of human genetics and development at the College of Physicians and Surgeons of Columbia University.

The author of more than 200 publications on many aspects of human genetics and microbiology, he is currently investigating the possibility that human breast cancer may be caused by a virus. Recently he detected the presence in human breast cancer of RNA homologous to mammary tumor virus RNA in mice.

A native of New York City, Dr. Spiegelman obtained his Ph.D. in cellular physiology from Washington University in St. Louis in 1944. He taught on the faculty at Washington until 1948, when he accepted a U.S. Public Health Service fellowship at the University of Minnesota.

A year later, he joined the faculty at the University of Illinois as professor of microbiology. After 20 years at Illinois, Dr. Spiegelman was appointed to his present position at Columbia in 1969.

The Edwin W. Schultz lectures honor the former chairman of Stanford's Department of Bacteriology and Experimental Pathology (now Medical Microbiology). Dr. Schultz taught at Stanford for 34 years, and served as chairman of his department from 1920 until his retirement in 1953.

A noted researcher in the field of virology, he published pioneering studies of poliomyelitis. He also directed an internationally sponsored medical training project at the University of Indonesia for seven years following his retirement from Stanford.

Dr. Schultz died last year at 83 following a long illness.

STANFORD -- Hospital nurseries should do everything possible to encourage the interaction of mothers and their premature infants, a Stanford University medical research team has recommended.

The traditional hospital practice of separating the mother and premature infant immediately after birth, for 3 to 12 weeks, has "a negative effect on maternal self confidence." This in turn may influence her subsequent relationship with her child, the researchers said.

Stanford University Hospital has adopted the recommendation and permits mothers to visit their babies in the premature nursery to engage in child care tasks.

Dr. P. Herbert Leiderman, professor of psychiatry, directed the four-year study conducted under the auspices of the Grant Foundation of New York and the National Institute of Child Health and Human Development.

He explained that due to the vulnerability of premature infants--their need for a controlled environment--trained medical personnel have in the past assumed the entire responsibility for fulfilling the child's physiological needs. Mothers have been denied the opportunity to learn and practice child care skills until the health and weight of their infants were adequate to permit transfer from the intensive care nursery to a discharge nursery.

Previous studies on the effects of mother-infant separation focused on the response of the infant rather than the attitudes and behavior of the mother. However, a variety of studies with non-human mammals indicate that a temporary separation "might deleteriously affect the female's subsequent maternal behavior."

The Stanford researchers postulated that the psychological effect of telling a mother that she is unable to provide the care her infant needs would be to lower her self-confidence, and that mothers of first-born would be particularly vulnerable.

The study was based on a modification of the Stanford University Hospital's procedure for the care of premature infants.

A group of 43 mothers--all with infants free of congenital abnormalities, fathers present in the home, and no previous history of premature or low weight births--were randomly divided into two groups. Members of the first group of 21 (the separation group) were able to view their infants through the nursery window, but denied all other contact.

The 22 mothers in the contact group were permitted to enter the intensive care nursery, and were able to interact directly with their infants--handling them, diapering them, and feeding them when the infant was able to suck.

The separation and contact phases of the study were alternated in blocks of 3 to 6 months, so that at any given time all mothers had the same experience, and believed it to be the normal procedure.

-more-

The pilot phase of the research demonstrated that it is possible to "introduce mothers into the premature nursery without clinically endangering the infant or disrupting the organization of care."

In addition to the 43 mothers of premature infants, 24 mothers of full-term babies were studied as a control. An attempt was made to match the group of full-term mothers to the mothers of premature infants with respect to social class, sex of the infant, and number of previous children.

The self-confidence of all mothers was analyzed through questionnaires, interviews, and observations conducted by professionals, from birth until 21 months after the infant was discharged from the hospital. The women were asked to evaluate their abilities to fulfill six care-taking tasks including calming the baby, understanding his wants, showing affection, and the instrumental activities of feeding, diapering, and bathing.

The results substantiated predictions by the research team. Although mothers of premature infants who had other children were not less self-confident even with the separation experience, mothers of first-borns who were premature "felt less capable in the usual care-taking tasks." Self-confidence was higher for those mothers permitted to interact with their infants, but remained critically low for mothers in the separation group.

One month after the infants were discharged from the hospital, the difference in self-confidence between the two groups of mothers with premature infants disappeared. However, Dr. Leiderman emphasized that these mothers all returned to intact family units, which is not likely to be the case for many mothers of premature infants.

He said, "We think the initial low self-esteem sets up a certain kind of vulnerability. At times of stress people tend to revert to earlier learned patterns. Thus, these mothers could become less self-confident and less involved in caring for their infants when experiencing stress.

Observations of the different groups revealed that mothers of premature babies spent less time in close physical relationships with their babies than mothers of full-term infants. The latter smiled and talked to their infants more frequently, exhibiting greater social responsiveness.

Dr. Leiderman said that although no differences were discovered in the physical or psychological progress of the infants involved in the study, the optimal development of a child is dependent on a caring individual who, in this society, is the mother. Any distance produced by virtue of separation in the hospital may lead to relative social barriers between the infant and his primary source of support.

"The significance of the study for the hospital staff," Dr. Leiderman concluded, "is a realization that what we do in the hospital does make a difference in how people relate to one another. Hospital routines must be made to fulfill the needs of people, not the needs of the efficient operations of the mechanical system."

The detailed report of the Stanford research is now in press. Collaborators in the study included Dr. Aimée D. Leifer of the Department of Psychology; Dr. Marjorie J. Seashore and Judith Williams of the Department of Psychiatry; Dr. Clifford R. Barnett of the Departments of Pediatrics and Anthropology; Mrs. Rose Grobstein of the Division of Social Work; and Dr. Marshall Klaus, a pediatrician formerly of Stanford and now at Case Western Reserve University in Cleveland.

STANFORD -- Dean Clayton Rich of the Stanford University School of Medicine, Friday (May 5) said he is prepared to recommend the addition of beds to Stanford University Hospital for leasing by the Palo Alto Medical Clinic.

At the same time, the dean said, he will recommend that the University lease land in the immediate vicinity of Stanford University Hospital so that the Palo Alto Medical Clinic can be relocated.

"This would give you access to beds at a predetermined and reasonable cost, and a clinic located in close proximity to the hospital, both of which you would need in order to have a hospital-based prepaid group practice," Dr. Rich proposed.

The Medical School plan which, if accepted, will require approval by the University Board of Trustees, was contained in a letter to Dr. Robert Jamplis, executive director of the Palo Alto Medical Clinic.

Dr. Rich said he considered the Medical School proposal "vastly more satisfactory" than an earlier Palo Alto Clinic plan to build a proprietary hospital and clinic at some distant location.

"By adding beds to Stanford rather than building a new hospital, we would avoid duplication of very expensive facilities and equipment and dissipating highly specialized personnel into two institutions," the dean wrote.

He added: "I believe that the quality of services and care provided to patients and the efficiency of operation would be strengthened by continuing to have the Stanford Hospital serve the entire community."

Dr. Rich said that at a meeting of the Medical School's executive committee April 7, "there was a positive opinion" for the proposed plan. "This was based on the high regard we have for the quality of medical practice and the contribution to medical education" that the Clinic staff makes to Stanford students, he said.

-more-

There was also strong concern that the construction of a second hospital in Palo Alto would cause unnecessary and undesirable duplication of very complex and expensive medical resources, Dr. Rich said.

The dean said the University and the community would be served better by one hospital which is outstanding rather than two hospitals, possibly both underutilized.

Stanford has all of the necessary hospital support facilities in operation, and a construction project will be shortly underway to improve laboratory facilities and to add 26 intensive-care beds to the hospital.

"It would be appropriate for us to extend this project by adding those facilities which would be necessary to meet your (Clinic) needs," Dr. Rich said.

The dean said that a request made by the Clinic on March 9 asking that land be leased at some distance from the Medical Center for construction of a proprietary hospital was also discussed by the executive committee. "There was much less enthusiasm for this proposal," Dr. Rich said.

If a separate hospital is the only possible course for the Palo Alto Medical Clinic, Dr. Rich said he would have to discuss the issue further with the faculty, particularly the question of land being used for this purpose.

"I do not reject this other possibility," Dr. Rich said, "but we would need your response to our offer before pursuing it further."

The Palo Alto Medical Clinic announced last fall that it would proceed with plans for a new hospital, separate from the Palo Alto Medical Research Foundation which had planned "a hospital of the future." The location of that hospital was rejected by Palo Altans at a city election two years ago.

Since then the Clinic had signed a contract with American Medicorp, Inc. which would have built and operated its proposed hospital after a site search and feasibility studies.

EDITORS: ADVANCE FOR PM RELEASE ON FRIDAY, MAY 5

STANFORD -- Does your doctor smoke pot?

If he's under 35 and lives in a large metropolitan area like San Francisco or New York, there's a good chance that he does, according to a survey conducted by two psychiatrists at Stanford University School of Medicine.

A significant number of practicing physicians have used marijuana, the researchers found. Results showed that of 1,314 doctors surveyed, 25 per cent had smoked marijuana in the past and 7 per cent called themselves current users.

Previous marijuana use ranged as high as 57 per cent among San Francisco Bay Area physicians under 35, to as low as 1 per cent among Nebraska physicians over 45.

The researchers, Drs. Martin R. Lipp and Samuel G. Benson, both residents in psychiatry at Stanford, reported their findings today (May 5) at the annual meeting of the American Psychiatric Association in Dallas, Texas.

The survey responses were obtained through questionnaires mailed and retrieved a year ago by the Department of Survey Research of the American Medical Association. Physicians in the study were chosen randomly from A.M.A. rosters in New York City, Upstate New York, Nebraska, and the San Francisco Bay Area. In all, 1,314 of 2,652 mailed questionnaires were returned.

Lipp and Benson emphasized that their data showed marijuana use is "very much a cultural issue, even among physicians.

"People in the health professions are creatures of our time," they said, "perhaps no more or less able to resist social phenomena than their neighbors and patients."

The discovery that a large number of doctors have used or currently use marijuana has special significance for the medical profession, Lipp and Benson noted.

"We can't simply call all marijuana users stupid or immature or crazy," they said. "Physicians must soon come to grips with the fact of marijuana use among themselves and cease talkingabout it as something that happens only to adolescents and patients.

"If medical authorities can't convince physicians to refrain from trying or using marijuana, convincing the public at large seems unlikely."

Of the 1,314 physician-respondents, 37 per cent had been exposed to marijuana (in a room or at an event where the drug was being used).

Usage of the drug varied according to age and geographical area.

-more-

"In general, the younger age groups are more likely to have tried marijuana in the past and to be using it currently," the authors said. "The San Francisco Bay and New York City areas show considerably greater use than do Nebraska and Upstate New York."

In the San Francisco area, 27 per cent of the physicians under 35 classified themselves as current users of marijuana and another 30 per cent had smoked it in the past. In New York City, 19 per cent under 35 were current users and another 21 per cent had past experience.

Meanwhile, only 1 per cent of physicians over 45 in Nebraska and 3 per cent in Upstate New York had any experience with marijuana.

The same four geographic areas had previously been surveyed by Lipp, Benson, and four other scientists in 1970 to obtain similar data from medical students. That study revealed that half of the 1,063 responding medical students had smoked marijuana and 30 per cent were current users.

The physicians in the most recent survey also provided information about alcohol and cigarette use. Only 8 per cent overall were non-drinkers, and 21 per cent currently smoked cigarettes.

The physician-respondents' medical opinion correlated with their marijuana experience and exposure. The most popular opinion (40 per cent) indicated marijuana was "relatively harmless in milder forms; should be graded according to strength and subjected to controls accordingly."

Professional reading was the most popular source of information for the doctors in forming their opinions about marijuana.

The research was supported in part by the Commonwealth Fund of New York.

STANFORD -- A pharmacologist from Stanford University Medical School called for the removal of lead from all gasolines today (May 4) in testimony before the Environmental Protection Agency (EPA).

"I strongly urge that lead be removed swiftly from all possible pollutants, including leaded gasoline, insecticides, additives for marine paints and other anti-fouling compounds," said Dr. Sumner Kalman, professor of pharmacology at Stanford. He made his remarks before an EPA hearing in Los Angeles on the issue of lead use in gasolines.

"Lead is a poisonous, persistent substance that we continue to deposit as an almost eternal film upon the earth and as particulate matter into the atmosphere," he said. "There is no simple way to clean it up. But we can stop putting it into the air by taking it out of gasoline."

Kalman emphasized the dangers of the current high levels of lead concentration in the air.

"Certain groups are placed unduly at risk as the amount of lead in the air continues to increase," he said. "These groups include the very young, and those with certain inherited metabolic diseases that might make them more sensitive to lead."

Lead-polluted air, he said, is implicated in lead poisoning in children, abnormal kidney function, and metabolic variances. These metabolic disturbances, particularly in the one to two million people in the United States with inherited metabolic disorders, can lead to harmful effects on the red blood cells.

Kalman also pointed toward the dangers of increased concentrations of lead which have recently been found in forage grass, especially near highways. He predicted that this will lead to toxicity among cattle and horses, and called for analyses of lead content in meat from grazing cattle.

Noting a "new dimension" of the problem, he said scientists have shown that levels of organic lead in sea water have increased, "endangering the survival of various so-called lower forms, in addition to ourselves."

Kalman testified on behalf of the Environmental Defense Fund, a national environmental group with local offices in Berkeley.

Editors: The full text of the PWSMS proposal and statement are available, if not included with story.

STANFORD -- Creation of an Office of Women's Affairs has been proposed by an organization of professional women at the Stanford University School of Medicine.

The new office would offer assistance to women to increase their contributions and improve their career opportunities. It would deal with problems affecting women in all branches of the health sciences, including women physicians and researchers, nurses, social workers, and physical therapists.

The proposal was submitted to Dean Clayton Rich, Wednesday (May 3) by the Professional Women of Stanford Medical School (PWSMS). This is an organization mainly composed of women M.D.'s and Ph.D.'s formed three years ago "to promote development of opportunities for women in the medical sciences."

Presently the Medical School operates an office devoted to development of career opportunities for women in medicine under the auspices of the Macy Foundation of New York.

"The Macy Office carries out part of the work we envision for the Office of Women's Affairs, but greater scope is needed," the PWSMS proposal stated. It added there was a need for an expansion of the role of the Office and a mechanism for continued function after the termination of Macy funding.

According to the document, the expanded functions of the Office of Women's Affairs would include counseling, recruiting of students and faculty, arranging for part-time work or study, and making possible a bigger role for women in medical affairs. The Office would also participate in a promotion review now under way at the Medical School, affecting many women in non-faculty positions.

The office, the proposal states, would be headed by a woman M.D. or Ph.D., appointed by a committee of faculty, administration, students and PWSMS. She would be assisted by an administrative assistant and a secretary.

In a prepared public statement Thursday, Drs. Ann Taylor and Dora Goldstein, PWSMS council members, suggested that a small part of the $5-million McCormick bequest to the Medical School might be an appropriate source of funding the new office. (The gift was made in 1969 by the late Mrs. Katharine Dexter McCormick in memory of her husband.)

The bequest, they said, contained the donor's wish that the money be used for the encouragement and assistance of women pursuing the study of medicine and engaging in medical research.

"Although the bequest indicated that 'needs and welfare of the School of Medicine' should be taken into account, many people believe that the donor intended the money to be used to bring about change in the status of women in the medical sciences," Drs. Taylor and Goldstein said.

"McCormick funds have been used to pay salaries of women already at the Medical School and the School of Nursing," their statement said, "yet no innovative programs have resulted from this bequest."

Dean Rich said he would study the PWSMS proposal and other recommendations and will make an appropriate response.

The dean commented that the Medical School had made substantial progress in the past two years in increasing opportunities for women to enter medical school. As a result of various faculty efforts, he said, the number of women in the entering class was increased from 9 per cent to 21 per cent last fall. Under Macy auspices, the Medical School has established a program of flexible internships and residencies for women.

At the same time, a joint committee of the School's Faculty Senate which included professional women had campaigned nationally and locally to increase the number of women. As a result, more women have been added to the medical faculty. ###

FOR IMMEDIATE RELEASE

STANFORD--

A new master of science degree program in Health Services Administration (HSA), perhaps the first of its type in the U.S. involving such a variety of disciplines, has been approved without dissent by the Faculty Senate at Stanford.

The interdisciplinary program will include the Schools of Medicine, Business, Engineering, and Humanities and Sciences. It will lead to a second graduate degree, a master of science, granted by the Department of Community and Preventive Medicine, for students already enrolled in other graduate curricula at Stanford.

The first class of 25 students is expected to begin study in Autumn Quarter 1973. Participants will be required to complete the HSA degree requirements in three academic quarters or less, depending upon previous course work, plus a three-month practicum at a health organization.

Program co-directors Count D. Gibson Jr., Department of Community and Preventive Medicine, and Nicholas Baloff, associate professor of business administration, believe it will help relieve the acute shortage of highly qualified professionals capable of assuming administrative roles in the newly emerging, sophisticated health delivery organizations proposed by President Nixon and members of Congress to combat the current national crisis in health care.

Financial assistance to developing and implementing the program is being sought from the Department of Health, Education and Welfare's National Center for Health Services Research and Development.

Baloff and Gibson foresee that the new specialty will fill the demand for administrators who are well versed not only in managerial concepts and techniques, but who also have an understanding of the sociological, "people" problems inherent in the new health organizations. The new program also is expected to provide a solid grasp of the practical applications of health systems research in day-to-day decision making.

The directors explain that through the multi-discipline environment provided by the HSA program, students will have the opportunity for the first time to follow a unified course of study in health services administration which draws on the increasing commitment by individuals within the cooperating schools to health systems research and the campus-wide movement by faculty and students toward socially involved, mission-oriented programs.

Gibson pointed out that the multitude of emerging health delivery organizations will have a mandate to provide a broader range of services than hospitals have traditionally delivered.

"The hospitals, with their orientation toward acute care, have been at one end of the health delivery spectrum," he said. "However, the health care system is also concerned with keeping people healthy and out of the hospital through preventive and ambulatory care.

"It is also concerned with making policy and planning on local, regional and national levels to meet the health needs of defined populations of people throughout the country." Therefore, an attempt is being made to educate men and women who can creatively manage all the resources available to them.

(more)

5/2/72 gr

Baloff noted that a graduate of the program would be qualified to work in health maintenance organizations, health care centers, preventive medicine, drug abuse centers, medical society foundations, hospitals, medical clinics, mental health facilities, and in governmental agencies such as HEW.

Providing specific examples of career paths for HSA graduates, Baloff said that a student with an engineering background would be qualified to bring his technical skills to the public sector, planning, designing and administering new health care systems.

The student from H&S would also bring his expertise to the health care field, initiating new programs and assessing the health care needs of a specific sector.

Dr. Clayton Rich, dean of the School of Medicine, agrees that "the need for well trained, research-oriented administrators with a variety of interdisciplinary backgrounds. . .will be very great in the next decade."

"The proposed program," Rich said, "could fill a niche not filled by schools of hospital administration and serve as a nucleus for very exciting research endeavors involving the different schools, the hospital, and medical agencies in the surrounding communities."

Arjay Miller, dean of the Graduate School of Business, said "one of the principal strengths of the program is its interdisciplinary nature For health services administration, with its broad social and technological implications, it is important that the schools of medicine and business be joined by humanities and sciences and engineering."

Miller also sees his school's participation as "an important extension of the Business School's activities in public sector management."

Closely associated with HSA from its earliest conceptual stages are Business Prof. John Moore and Medical Prof. John C. Hershey.

During the past two and one-half years, Baloff and Gibson have jointly headed a team of researchers from the Business and Medical Schools who are developing a management information system to provide health administrators, regional health planners, and federal policy makers with practical information with which decisions about operating health facilities, planning future health care needs and evaluating quality of health care delivery can be made.

Currently they are testing their management information system at a small community-owned and controlled health center in Livingston, San Joaquin County. After a successful demonstration there, the system is expected to become a model for health care centers around the country.

STANFORD -- Paul B. Hofmann, associate administrator of San Antonio Community Hospital in Upland, Calif., has been appointed deputy director of Stanford University Hospital.

The announcement was made today (May 2) by Dr. Thomas A. Gonda, director of the Hospital.

The appointment, which followed a nationwide search of several months, becomes effective June 1.

Hofmann, 30, has been at San Antonio Hospital for three years. After serving a year as assistant administrator, he was promoted to associate administrator of the hospital in July of 1970. For the past two years he has also served on the faculty of the UCLA School of Public Health as a lecturer in hospital administration.

An expert in the applications of computer technology in hospitals, Hofmann has published nine articles in professional hospital journals over the past four years.

He received his B.S. in 1963 and his Master of Public Health degree in 1965 from the University of California in Berkeley. After further administrative training, he was assistant director of the Laboratory of Computer Science at Massachusetts General Hospital and instructor in computer applications at the Harvard School of Public Health before joining the staff at San Antonio.

The position of deputy director at Stanford has been vacant since July of last year, when Frank R. Vitale resigned to accept a partnership with a national hospital consulting firm.

STANFORD -- Dr. Lawrence G. Crowley, professor of surgery at Stanford University School of Medicine, has been appointed associate dean for planning, Dean Clayton Rich announced today (June 28).

Dr. Crowley's appointment to the newly established position becomes effective July 1. He will have responsibility for coordinating the short- and long-range planning efforts of the Medical School, both in academic activities and in the development of new facilities.

Currently chief of surgery at the Palo Alto Veterans Administration Hospital, he has been instrumental in developing an effective clinical teaching service at the V.A. Hospital.

Dr. Crowley came to Stanford in 1964 as associate professor of surgery. He has done extensive research on breast cancer and the biochemistry of human tumors.

A native of Newark, New Jersey, he received both his B.A. (1941) and M.D. (1944) degrees from Yale University. After serving his internship and residency at New Haven Hospital, he taught on the faculty at Yale for two years.

Prior to his appointment at Stanford, he was in private surgical practice and was attending surgeon at the Los Angeles County General Hospital and Pomona Valley Hospital.

STANFORD -- Two faculty members and a former member of the Division of Physical Therapy at Stanford University School of Medicine were honored recently at the annual conference of the American Physical Therapy Association (APTA) in Las Vegas.

Lucille Daniels, associate professor of physical therapy, received the Mary McMillan Lecture Award for 1973. The award, named after the first president of the APTA, is one of the highest honors for physical therapists. Miss Daniels will deliver the ninth annual lecture at next year's APTA conference in Houston.

Miss Daniels was director of the Division of Physical Therapy for 25 years, beginning in 1946. In 1971 she relinquished her administrative responsibilities to have more time for teaching and research.

Barbara Kent, assistant professor of physical therapy, was presented the Golden Pen Award for an outstanding contribution to Physical Therapy: Journal of the APTA. Her article, "Functional Anatomy of the Shoulder," appeared in the August, 1971 issue.

The division's first director, Dr. Catherine Worthingham, was given honorary membership in the APTA, of which she is a past president. Dr. Worthingham was head of the Physical Therapy Division from its establishment in 1941 to 1945. She was subsequently director of professional education for the National Foundation (March of Dimes). Now she is retired and lives in Connecticut.

Dr. Worthingham has been at Stanford to work with Miss Daniels on the third edition of a textbook they co-authored. The book, Muscle Testing, is a standard physical therapy text throughout the world.

The Division of Physical Therapy is part of the Medical School's allied sciences program. Its training program for physical therapists leads to a master's degree after two years. Students can specialize in physical therapy administration, teaching, community health or pediatrics. Research in the division centers around muscle function and testing.

STANFORD -- Dr. Kendric C. Smith of Stanford University has been elected president of the newly formed American Society for Photobiology.

The new society was founded by the committee on photobiology of the National Academy of Sciences, National Research Council.

Dr. Smith, a biochemist in the department of radiology of the Stanford University School of Medicine, is a leading expert in the field of photobiology which deals with the chemical and biological effects of light.

Other society officers include Dr. Angelo A. Lamola of Bell Telephone Laboratories, Murray Hill, New Jersey, vice-president; Dr. Edwin W. Abrahamson of the department of chemistry, Case Western Reserve University, Cleveland, secretary; and Dr. Leo Preston Vernon, director of research at the Brigham Young University, Provo, Utah, treasurer.

Dr. Smith said that solar radiation is probably the most important element in our environment and yet, perhaps because of its ubiquity, the wide scope of its chemical and biological effects is often not fully appreciated.

"Research has been performed on the effects on man of other environmental factors such as temperature and pressure, yet very little research has been performed on the effects of light (beneficial and detrimental) on man and his environment," he said.

The American Society for Photobiology plans to take an active role in educating society in general about the unique properties of light, Dr. Smith continued. It also plans to make available information on the photobiological and photochemical aspects of national and international problems.

The Stanford biochemist described several national problems whose solutions will depend on accurate photobiological information. Examples included:

. the possible damage of the ozone layer of the earth's atmosphere by supersonic transport aircraft and the consequences of increased ultraviolet radiation to man and the environment.

. development of more effective methods for using visible light irradiation for treatment of premature babies with congenital jaundice.

. the effects of pesticides on man. Only recently has the question been raised as to the toxicity of pesticide molecules that have been altered photochemically by sunlight.

Photobiology is currently subdivided into several specialized research areas. They are bioluminescence, chronobiology, environmental photobiology, medicine, photochemistry, photomorphogenesis, photomovement, photoperception, photosensitization, photosynthesis, phototechnology, spectroscopy, ultraviolet radiation effects, and vision.

"One goal of the new society," Dr. Smith said, "is to provide a basis for communication, that is presently lacking, between scientists in these different areas of photobiology through annual scientific meetings and publications."

The Society will hold its first scientific meeting at Sarasota, Florida June 11 through 14, 1973, on the theme of Light and the Quality of the Environment.

STANFORD -- A 53-year-old Massachusetts man became the 45th heart transplant patient at Stanford University Hospital last night (June 21). He is now listed in fair condition.

The operation was performed by a team of surgeons headed by Dr. Norman E. Shumway.

The patient has been suffering from coronary artery disease. In accordance with Hospital policy, his name and the name of the donor will be withheld.

Including the new recipient, 17 of the 45 heart transplant patients operated on at Stanford Hospital are now living.

STANFORD -- An increase in daily room rates beginning June 25 was announced Thursday (June 21) by Stanford University Hospital.

For community patients the daily room rates will now be $69 for medical and surgical wards. Semi-private rooms will be $75 and private rooms $84.50.

This represents an increase of $4.50 for ward and semi-private rates, and $5 for private rooms. A year ago there was an overall increase of about four dollars in daily rates, and the year before there was a flat $5.50 increase.

Obstetrical ward rooms will now be $70.50 daily, with nursery rooms $49.50. Coronary care units will be $195 daily.

The new rates represent an overall increase of 5.5 per cent, which falls under the 6 per cent Price Commission guideline, hospital officials pointed out.

The increase in rates was attributed by Hospital Director Dr. Thomas A. Gonda to the continuing rise in the cost of wages for personnel and materials.

STANFORD -- A tiny infant flown to Stanford University Hospital Tuesday (June 20) from Montana, is stable and in satisfactory condition, doctors report today.

Jason Scruggs, a one-month-old premature baby from Great Falls, Montana, was raced to the Hospital's newborn intensive care unit by ambulance after an Air Force jet brought him to Moffett Field.

He has lung disease and is being treated for a possible lung infection, according to Dr. Birt Harvey, clinical assistant professor of medicine at Stanford.

The infant, who weighs 4 pounds 12 ounces, had hyaline membrane disease when he was born. This respiratory difficulty seemed to have cleared up, but it is conceivable that the infant's current problems are complications of that earlier disease, explained Dr. Harvey. He said that the infant also has a heart problem, but that too may clear when his lungs are better.

Dr. Harvey, a specialist in pediatric chest problems, became involved in Jason's case when he was called by a relative of the Scruggs family to ask if Stanford could help the baby. Monday night the infant's physician in Great Falls called to say Jason's condition seemed critical.

An Air Force "med-evac"plane, which is part of the Military Airlift Command, was made available from Scott Air Force Base near St. Louis. The medical plane, specially equipped with an incubator, flew to Montana to pick up the infant and his parents, Donald and Pamela Scruggs.

Members of the Stanford infant transport team met the plane at Moffett Field, where they transferred Jason to an infant transporter and waiting ambulance.

STANFORD --- Twenty-nine Spanish speaking employees of Stanford University Hospital were honored for their English language skills at a banquet Sunday evening, June 17.

Dr. Thomas Gonda, Hospital director, awarded them certificates for completing English language classes. He made the presentation in ceremonies at La Fonda restaurant in San Jose.

The courses are provided for employees as part of the Hospital's work-study program, headed by Tony Rodriguez. The program was launched last year to coordinate staff education and training.

Conversational English classes are offered to employees who want to improve their language abilities so they can take advantage of more advanced training opportunities. For the most part, schooling is conducted on the Hospital premises and employees are paid for the time they spend in the classroom.

Recipients of certificates were:

From Palo Alto: Prudencio de la Cruz, Dietary; Romulo Alvarez, Housekeeping; Eduardo Begines, Housekeeping; Felipe Cornelio, Dietary; Ruben Hernandez, Housekeeping; Jose Rivero, Dietary; Eliseo Aguilar, Dietary; Josephine Garza, Personnel; Carlos Gimenez, Messenger Service; Luz Gonzales, Psychiatry; Refugio Guzman, Dietary.

From Redwood City Rigoberto Alvarez, Dietary; Carolina Ortiz, Housekeeping; Jose Lopez Villacorta, Housekeeping; Jose Luis Diaz, Housekeeping; Rosa de la Peña, Dietary; Mario Perez, Dietary; Ester Ponce, Housekeeping; Ymelda Torres, Housekeeping; Maria Villicaña, Housekeeping; Rigoberto Arreola, Housekeeping; Thomas Boukaka, Laboratory Animal Medicine; Aurora Sosa, Housekeeping; Vilandre Volcinus, Housekeeping; Carmen Medina, Housekeeping.

From San Jose ---David Zacarias, Housekeeping; Jose M. Zacarias, Housekeeping.

From San Francisco---Clarita M. Ignacio, Surgery.

From Atherton ---Cirenio Sosa, Housekeeping.

In addition, the work-study program presented four special certificates for outstanding contributions to Carol Hayes, director of Dietetics; Ernest Hultman, executive housekeeper; and instructors Kathleen Colyer and Mitchell Hall. Rodriguez also thanked Dr. Gonda and Donald Utt, associate director, for their cooperation and support of the courses.

Photos available on request.

ADVANCE FOR PM RELEASE ON THURSDAY, JUNE 22

STANFORD -- Dr. Luigi L. Cavalli-Sforza, professor of genetics at Stanford University School of Medicine, today (June 22) was awarded the Thomas Henry Huxley Medal from the Royal Anthropological Institute of Great Britain and Ireland.

The medal is awarded annually to a scientist distinguished in any field of anthropological research.

Dr. Cavalli-Sforza was honored for his contributions in genetics research, particularly his work in human population genetics.

His research has focused on the role of chance in determining human evolution, and the development of models and methods for the study of evolutionary relationships between different human populations. He recently co-authored a book with Dr. Walter Bodmer, formerly of Stanford, The Genetics of Human Populations, published by W. H. Freeman.

He is also noted for his work in bacterial genetics which laid the foundation for a better understanding of the genetics of drug resistance in bacteria.

A native of Genoa, Dr. Cavalli-Sforza received the M.D. degree with honors from the University of Pavia in 1944. He was a research fellow and assistant in genetics at the University of Cambridge from 1948-50, and studied at the University of Wisconsin as a Rockefeller Fellow in 1954.

After seven years as director of research in microbiology at the Istituto Sieroterapico Milanese, he was appointed professor of genetics at the University of Pavia in 1958.

Prior to his appointment to his present position in February of 1971, Dr. Cavalli-Sforza was a visiting professor at Stanford on several occasions.

The Huxley Medal was established in 1900 in memory of Thomas Henry Huxley, famous English biologist who died in 1895.

STANFORD -- Dean Clayton Rich of the Stanford University School of Medicine today (June 12) appointed three new associate deans to coordinate the School's community-related academic programs.

They are Dr. R. Morton Manson of San Jose; Dr. Franklin G. Ebaugh, Jr. of Salt Lake City, Utah; and Dr. Edward Rubenstein of San Mateo.

Dr. Rich said the appointments reflect "a recognition of the central role of community-based programs in the education of future physicians at Stanford."

Dr. Manson will coordinate academic activities of the Medical School at the Santa Clara Valley Medical Center (SCVMC). The Center, which signed a formal affiliation agreement with Stanford -- recently, provides a teaching environment and services for medical students and residents. Dr. Manson's appointment becomes effective September 1.

Dr. Ebaugh will take up his new duties July 1. He will coordinate Stanford's programs at the Palo Alto Veterans Administration Hospital and will serve as chief of staff, senior attending physician and clinical professor of medicine. An important portion of Stanford's teaching and research program is carried out at the VA Hospital staffed by full-time faculty members.

Effective immediately, Dr. Rubenstein will become an associate dean for postgraduate education. He will direct development of lifelong education programs for physicians in practice.

A 1945 alumnus of the Stanford medical school, Dr. Manson is currently director of SCVMC's clinical services, and an assistant director of the Department of Medical Institutions of Santa Clara County. The 53-year-old internist has also served as a clinical assistant professor of medicine, and has been instrumental in the development of clinical teaching and faculty development programs at SCVMC.

Dr. Ebaugh, 50, is a native of Philadelphia. He is former dean of Boston University School of Medicine, and University of Utah School of Medicine. He is currently a professor of medicine specializing in hematology, and chairman of the VA dean's committee at Salt Lake City. He is graduate of Dartmouth College, and holds a medical degree from Cornell Medical College. He was also associate director of laboratories of the Hitchcock Clinic and Mary Hitchcock Hospital and an associate professor of clinical pathology at Dartmouth Medical School from 1955 to 1964.

Dr. Rubeinstein, 48, is a lecturer and clinical professor of medicine, and served as chief of Stanford's medical service at San Mateo County General Hospital from 1960 to 1970. He was born in Cincinnati and was graduated from the College of Medicine in 1947. He is author of the texbook, "Intensive Medical Care." As chairman of Stanford's postgraduate medical education committee, Dr. Rubenstein developed a decentralized education program for physicians in practice, using area community hospitals as centers for teaching. Another effort under way is a Back-to Medical School program. It permits physicians to keep up with medical advances by re-entering Stanford medical school and "graduating" a second time.

STANFORD -- Eight graduating students and 15 faculty members were honored at the annual convocation of Stanford University School of Medicine Sunday evening (June 11).

Diplomas were presented to 75 medical graduates, 7 women and 68 men. Another 43 graduates received advanced degrees in the basic medical sciences.

Master's degrees went to 20 graduates, including 11 women and 9 men. Doctoral degrees were presented to 3 women and 20 men. The School of Nursing awarded diplomas to 26 women.

F. Wells Shoemaker, Jr. received the Robert H. Alway Book Award, given to the "student in the graduating class who has best availed himself of the unique opportunities afforded by Stanford's five-year plan." It is named in honor of Dr. Alway, dean of the School of Medicine from 1958 to 1964.

The Robert deMailly Award was awarded to Bruce Wermuth. Established in memory of Dr. deMailly in 1957, it is presented to the "senior medical student who has distinguished himself in gynecology and obstetrics."

William Mitchell won the Harold K. Faber Award for "his outstanding accomplishment as a student of pediatrics and his potential as a contributor to child health." The award was established in 1964 by the pediatrics faculty to honor Dr. Faber, professor emeritus of pediatrics.

Recipient of the Robert J. Glaser Book Award was Dennis McShane. The award is presented in "recognition of Dr. Glaser's contributions as dean of the School of Medicine (1964 to 1970) to a graduate who had displayed outstanding characteristics of leadership."

Carol Portlock was presented the Janet M. Glasgow Memorial Award of the American Medical Women's Association which is given to "the senior woman medical student considered by her school to be outstanding in her class."

The L.A. and Marion S. Hopkins Award to the outstanding senior medical student in dermatology was presented to Gary Feldman.

John Vierling, "who has distinguished himself in the field of infectious disease," received the Lowell A. Rantz Memorial Award, established in 1967 to honor the memory of Dr. Rantz, professor of medicine. Vierling also won the Robert M. Shelton Memorial Award of the Stanford Medical Alumni Association.

-more-

Graduation

Mary Alice Helikson was awarded the Upjohn Achievement Award for "outstanding clinical performance."

Four faculty members, two in the basic sciences and two in the clinical sciences, won the Henry J. Kaiser Award for excellence in teaching. They were: Drs. Robert Archibald, visiting assistant professor of pathology; Gerald Levine, assistant professor of pathology; Roy Maffly, professor of medicine and Stanley Schrier, associate professor of medicine.

Ten other faculty members received honorable mention. They included: Drs. Paul Berg, Jack, Lulu and Sam Willson Professor of Biochemistry; Robert Lehman, professor of biochemistry; Gerald Reaven, professor of medicine; Eugene Robin, professor of medicine, and Maureen Sass, instructor in anatomy. Also Drs. John Frenster, assistant professor of medicine; John Johnson, assistant professor of pediatrics; Halsted Holman, Berthold and Belle N. Guggenhime Professor of Medicine; R. Naomi Remen, assistant professor of pediatrics and Paul Wolf, associate professor of pathology.

The awards were presented by Grace Ringressy, professor and director of the School of Nursing, and Dr. Clayton Rich, dean of the School of Medicine.

Representing the senior class, Paul Rutala presented the Arthur L. Bloomfield Award for excellence in teaching of clinical medicine to Dr. Ernest Lowe, associate professor of gynecology and obstetrics.

The main address was delivered by Dr. LeRoy Pesch, a former associate dean of the School of Medicine, and currently president of Michael Reese Hospital and Medical Center, Chicago.

Award winners and their parents' addresses are listed below:

CALIFORNIA	William Mitchell, son of Mr. and Mrs. Roy F. Mitchell, 152 Alderbrook Dr., Santa Rosa 95405;
	Carol Portlock, daughter of Warren E. Swanson, 8040 W. 83rd, Playa del Rey and Mrs. Joan S. Redlich, 673 Georgetown Ct., Sunnyvale;
	John Vierling, son of Mr. and Mrs. Lester H. Vierling, 439 Catalina Dr., Newport Beach;
ILLINOIS	Dennis McShane, son of Mr. and Mrs. James McShane, 734 Suffolk, Westchester;
NEW JERSEY	Bruce Wermuth, son of Mr. and Mrs. Walter M. Wermuth, 30 Valley View Rd, Verona 07044;
OREGON	Mary Alice Helikson, daughter of Mr. and Mrs. Dale Helikson, 720 E. 2nd, Oakridge;
PENNSYLVANIA	Gary Feldman, son of Mr. and Mrs. Dan Feldman, 3323 Shady Ave Ext. Pittsburgh 15217;
	F. Wells Shoemaker, son of Mr. and Mrs. F. Wells Shoemaker, R.D. #4, Carlisle 17013.

STANFORD -- Dr. Irving Schulman, an internationally known expert in blood diseases of children, has been appointed professor and chairman of the department of pediatrics at the Stanford University School of Medicine.

Dr. Schulman has been professor and head of the department of pediatrics at the University of Illinois College of Medicine in Chicago since 1961.

His appointment, announced Monday, (June 12) by Dean Clayton Rich, will be effective September 1. Dr. Schulman will succeed Dr. Robert H. Alway, professor of pediatrics, who served in an acting capacity during the year-long search for a new chairman.

The 49-year-old pediatrician was born in New York City. He attended public schools there and received the B.A. from New York University in 1942, and the M.D. from New York University College of Medicine in 1945.

Dr. Schulman said one of his challenges at Stanford will be to identify the needs of children who require specialized care in Northern California, but who are not getting it. Another need will be to increase programs for prenatal diagnosis.

The largest cause of mortality in children after accidents is malignant disease, he explained. Birth defects, developmental aberrations, and disorders of the immune system also represent significant problems. "There is a whole spectrum of hereditary defects which require study, understanding, amelioration and prevention," the pediatrician said.

Dr. Schulman emphasized he looks forward to developing closer ties with the Children's Hospital at Stanford. "This step is highly desirable and will be of mutual benefit to both institutions and the children who will be treated there," he said.

Although it has excellent facilities and is located nearby, this hospital is not utilized fully for teaching by the Medical School.

-more-

Dr. Irving Schulman

222

Dr. Schulman's research is in coagulation physiology and hemorrhagic diseases such as hemophilia. He is currently investigating the basic cause of the excessive tendency of some newborn babies to bleed, and its relationship to mental retardation. Specifically, the work deals with one of the smallest and lightest elements in the blood called platelets, which are essential for the clotting process. Platelet function is defective in some newborn babies. Finding out why has implications for preventing bleeding in newborn babies, and thromboembolic disease in adults, he believes.

Dr. Schulman interned at Queens General Hospital in New York City, and completed his residency in pediatrics at Bellevue Hospital in 1949. He served as a U.S. Public Health Service postdoctoral fellow in pediatrics at Cornell University Medical Center, and joined the faculty there in 1952. In 1958 he was appointed associate professor of pediatrics at Northwestern University Medical School, and in 1960 he was promoted to professor.

He is the author of nearly 80 papers in his field, contributor to three medical textbooks, and editor-in-chief of an annual volume titled Advances in Pediatrics.

In 1960 he won the Mead Johnson Award for Pediatric Research, and in 1968 the John F. Kennedy Award for distinguished service to children from Georgetown University. He also won awards for outstanding teaching by the junior class of the University of Illinois College of Medicine in 1963 and 1970. This year he received the University of Illinois College of Medicine Distinguished Faculty Award.

Dr. Schulman is a diplomate of the American Board of Pediatrics, a fellow of the American Academy of Pediatrics, and a member of the Society of Pediatric Research, American and International Societies of Hematology and American Society for Clinical Investigation among others.

Dr. and Mrs. Schulman have two children, a son 12-1/2 and a daughter, 16. Mrs. Schulman, a Cornell University graduate, is presently a librarian at Hadley School for the Blind at Winnetka, Illinois. The Schulmans plan to live on the Stanford campus.

STANFORD UNIVERSITY NEWS SERVICE

STANFORD, CALIFORNIA 94305
(415) 321-2300, Ext. 2558
Southern California office: (213) 627-0653

Fire of undetermined origin caused several hundred thousand dollars damage to Encina Hall, Stanford's main administrative building, Wednesday night, June 7. There were no injuries.

The fire apparently started in the attic of the four-story structure. The initial alarm was sounded around 9 p.m. The blaze was brought under control about two hours later, with help from about 100 firemen from Palo Alto, Los Altos, Mt. View and Sunnyvale. Eighty more began the cleanup at 1 a.m.

Stanford Fire Chief Frank Jurian estimated the damage would run to "several hundred thousand dollars."

The most heavily damaged portion of the building was the East Wing, which houses the Personnel Office and Health Physics Office. The fire broke through the attic there to the fourth and third floor, which were soon to be remodeled, and were vacant. The first and second floors had water and smoke damage.

The fire destroyed the attic of the central portion of the building, but did not break through to offices there. "We were very, very fortunate" the fire was contained, Chief Jurian said. Offices there suffered water and smoke damage. The central portion was remodeled in the late 1950's.

The West Wing, which had been remodeled in 1970 to house the Food Research Institute, appeared undamaged. Encina was built in the 1890's as a dormitory.

Following a post-midnight inspection of the building, top administrative officials said major University functions would continue almost without interruption.

Vice President Robert R. Augsburger said all supervisory personnel in Encina were being asked to report for work Thursday, June 8. Other employees in Encina were asked to remain on call, and their pay will continue.

Provost William Miller, who accompanied Augsburger and other officials on the inspection, said "The basic work of the University will continue despite this temporary interruption to some administrative functions. The academic program and all other University operations will not be interrupted."

The closing of all portions of Encina to employees is temporary until the County Fire Marshal and Stanford plant engineers are able to complete their work, Augsburger said. Encina Commons offices remain in full operation.

Temporary locations for the Personnel and Health Physics Offices, and other units in the East Wing of Encina, are being selected and will be announced as soon as possible.

STANFORD -- Dr. Theodore W. Loring of Eureka, California, is the new president of the Stanford Medical Alumni Association, and Dr. Wilbur B. Hurlbut of New York City, is the new president-elect.

Dr. Loring assumed his new duties Saturday (June 3) at the conclusion of the Spring reunion of the Association on the campus. He will serve as president through July, 1973. Dr. Loring specializes in obstetrics and gynecology, and received his medical degree from Stanford in 1946. He also served on the Association's board of governors and many of its committees.

Dr. Hurlbut specializes in dermatology in New York City. He is an attending physician at Roosevelt Hospital, a member of the executive board, of the committee on public health of the New York Academy of Medicine, and a member of the Visiting Committee of the Stanford University School of Medicine.

Newly elected members of the board of governors of the Association include Dr. Frances K. Conley of Palo Alto, and Dr. John Minna of Bethesda, Md.

Dr. David A. Rytand of Atherton was re-elected secretary-treasurer.

STANFORD -- Four students of Stanford University School of Medicine were named Alumni Scholars for 1972 by the Stanford Medical Alumni Association.

They were presented awards at Alumni Day Ceremonies Saturday (June 3). Eight other medical students who were candidates for the award were presented the Book Award.

Alumni Scholar Award winners were: Maida Taylor, Year II; Randall Morris, Year III; John Williamson, Year IV; and John Vierling, Year V.

The Alumni Scholar Award was established in 1965 by the Stanford Medical Alumni Association to honor a medical student in each of four upper classes. Recipients are selected "primarily on the basis of high scholastic achievement," but consideration is also given to"qualities of leadership, excellence of character and promise of becoming a doctor who will render superior service."

Last year, the award given to the fifth year student was designated the Robert M. Shelton Memorial Award Award to honor the late Dr. Shelton, a distinguished medical school alumnus and past president of the Alumni Association.

Second, third and four year class Alumni Scholars receive $600, and the fifth year class winner receives $750.

Award winners and their parents' names and towns are listed below:

Alumni Scholars:

New York	Maida Taylor, daughter of Martin and Muriel Taylor, Plainview
California	John Vierling, son of Lester and Ruth Vierling, Newport Beach
	Randall Morris, son of Mr. and Mrs. Walter Morris, Hillsborough
Oklahoma	John Williamson, son of R.D. and Jacqueline Williamson, Tulsa

Book Award Winners:

California	Rodney Ellis, son of Roy and Delores Ellis, San Francisco
	Stephen Nimelstein, son of David Nimelstein, Northridge
	Thomas Raffin, son of Bennett and Caroline Raffin, San Francisco
	Kenneth Yamada, son of Dr. and Mrs. Paul Yamada, Los Altos
New York	Ron Rosenfield, son of Stanley and Deborah Rosenfield, Elmont
Ohio	Sharon Hunt, daughter of Edward and Bernice Hunt, Northfield
Pennsylvania	Charles Caplon, son of Irving and Rosalie Caplon, Pittsburgh
Washington	John Ordal, son of Erling and Lorna Ordal, Seattle

STANFORD -- Richard L. Balch, vice-chancellor for university relations at the University of California, San Francisco, has been appointed associate dean for administration and assistant to the vice-president for medical affairs at Stanford University School of Medicine.

The appointment, which becomes effective September 1, was announced today (July 31) by Dean Clayton Rich.

Balch, 53, succeeds Robert G. Lindee, who resigned July 1 to become vice-president of the Henry J. Kaiser Family Foundation.

A 1941 graduate of Union College in Schenectady, New York, Balch did graduate work at both Union College and Stanford, and later spent a year as a visiting fellow at Harvard Business School.

Twice in the past he has served as an administrator at Stanford, first as dean of men from 1947-55. After six years as associate dean of students and director of athletics at Massachusetts Institute of Technology, he returned to Stanford in 1961 as associate director for development.

He was appointed vice-chancellor for student affairs at the University of California at Irvine in 1964, and then served as director of the Peace Corps in the Philippines for one year. From 1967-70, Balch was vice-president for continuing education and community service at the University of Hawaii. He was appointed to his present position a year ago.

Balch and his wife, Patricia, have two children and reside in San Francisco.

STANFORD -- Stanford University has received a bequest valued in excess of $700,000 from the estate of Mrs. Fannie B. Dore, it was announced today by Dr. Clayton Rich, vice president for medical affairs and dean of the Medical School.

Half the amount thus far distributed is to be used for research in cardiovascular and renal diseases, and half is to be added to the Charles B. Doré Memorial Fund at the Stanford Medical School.

Established in 1955, this Fund provides support for faculty salaries and fellowships in the same two fields of medical research.

The current distribution brings to over $1 million the amount received to date for use in the Stanford University School of Medicine from Mr. and Mrs. Dore.

Mr. Dore, who died in 1955, was formerly vice president of Superior Oil Company and prominent for many years in the Bakersfield area. Mrs. Dore died in 1971.

In accepting delivery of the bequest from Bakersfield attorney Curtis Darling, Dr. Rich said, "We are greatly indebted to Mrs. Dore for providing this valuable support to Stanford's medical research activities in these two vital areas.

"This newest addition to the Charles B. Dore Memorial Fund will also provide added strength to our faculty and training programs, and will make possible the advancement of knowledge about these diseases. It is an honor for Stanford Medical School to receive such generous assistance, and we look forward to substantial accomplishments in the future."

Editors: Copies of Stanford M.D. available on request if not included with story.

STANFORD--Married couples, who think they can engage freely in any variety of lovemaking in the privacy of their homes, risk criminal prosecution under ancient laws which govern sexual behavior in the United States, according to two Stanford University psychiatrists.

"Almost all sexual activity that may occur between husband and wife, with the exception of kissing, caressing and vaginal intercourse, is defined as criminal in virtually every state of the union," said Drs. Herant A. Katchadourian and Donald T. Lunde.

People are either unaware of these laws or think they are largely "dead" and so rarely enforced as to be inconsequential, the psychiatrists said.

"But their very existence on the books allows for their occasional and capricious application," they continued. "This ill serves the interests of society, the individual and the law."

Katchadourian and Lunde made their comments in an article in the current issue of Stanford M.D., the magazine of the Stanford Medical Alumni Association. The article is based on their new book, Fundamentals of Human Sexuality just published by Holt, Rinehart and Winston, Inc.

"It is unlikely that the average married man suspects that his marital sexual activity will ever be held against him," Lunde said. "Even if he knows that a certain behavior is illegal, as long as he and his wife perform it in private, who can substantiate the charge?" In practice, however, it doesn't work this way. He gave this example:

In 1965, a woman in Indiana quarreled with her husband of 10 years, and filed a complaint of sodomy against him. She did not accuse him of having used force. Before the case came to trial the woman changed her mind and sought to withdraw the charge. She was not allowed to do so because sodomy is an offense against the state, and the state proceeded to prosecute. The man received a prison sentence of from 2 to 14 years. After serving three years, he was released when a higher court overturned his conviction on a technicality in the proceedings.

Sex laws even meddle with the frequency of intercourse between a married couple, said the psychiatrists. For example, if no intercourse at all has occured, the law provides for annulment of the marriage on these grounds.

"A man's impotence or a woman's refusal to engage in sexual intercourse with her husband have long been held sufficient grounds for annulment," they wrote.

"Our society is unique in many aspects of its sex laws, expecially those defining sexual intercourse between unmarried consenting adults as criminal behavior," the psychiatrists commented. "Other societies may condemn it as immoral, some may set limits on it, and others may encourage it. Yet most of our states define it as a crime."

-more-

222--Sex Laws

Sex laws in America reflect a particular Judeo-Christian point of view of sexual behavior, the psychiatrists explained. The sole purpose of sexual activity is reproduction. Other notions arising from the ethical and religious backgrounds of the founders of Anglo-American society are also embodied in law, including the opinion that sex is evil.

As a result "our laws seem to be more preoccupied with prohibiting the stimulation of sexual activity than with prohibiting the stimulation of aggressive violent behavior," Katchadourian and Lunde wrote.

Citing the Kinsey report which shows that more than 95 percent of men have at some point engaged in sexual acts prohibited by criminal laws, the psychiatrists describe how existing laws are usually enforced and present arguments for and against their retention.

Sexual intercourse between consenting unmarried adults is prohibited by law in most states, wrote the psychiatrists. The offense is usually a misdemeanor, punishable by a fine, which may be as small as $10 (Rhode Island) or as large as $500 (Texas). In Arizona, however, the statute defines the offense as a felony punishable by imprisonment for no more than three years.

California has a seduction law which stipulates that "a person who seduces and has sexual intercourse with an unmarried female of previous chaste character" can receive a maximum prison sentence of five years and pay a fine of up to $5,000 or both.

Of course, the male can usually escape prosecution for seduction by marrying the girl, the psychiatrists note, but if she is under age, the culprit may still be prosecuted for statutory rape.

The concept of statutory rape is equally confusing, the psychiatrists pointed out, because it is based on the age of the girl which varies from 14 to 21, depending on the state. But only the male is regarded guilty, even if the girl has been a willing partner.

Katchadourian and Lunde side with the majority of criminal lawyers in attacking the absurdity of some of the sex laws. These authorities feel that all sexual activities in which married couples engage in the privacy of their homes should be legalized.

Like the lawyers, however, the two psychiatrists make a distinction between sex laws that should be retained and laws that should be repealed. Laws governing rape, child molesting and generally offenses involving violence should continue, they believe.

Mailed Thursday, July 13, 1972

Stanford psychiatrists Donald T. Lunde and Herant A. Katchadourian have attacked ancient laws which govern sexual behavior of married couples in the privacy of their homes. "People are unaware of laws that define everyday sexual experiences as crimes, Lunde and Katchadourian said. They are often applied capriciously to the detriment of the individual and society. 7/13/72.

STANFORD--Dr. Eugene M. Farber of Stanford University has received the Order of Jose Maria Vargas from the Central University of Venezuela. He is the first scientist from North America to receive the award.

Dr. Farber is an internationally known expert in psoriasis and professor and chairman of the department of dermatology at Stanford medical school. He was honored for his scientific contributions to dermatology and the development of the medical curriculum at Central University.

The Vargas award is the highest honor the Central University can give, according to the citation. It was established in honor of Jose Maria Vargas, a physician and former president of Venezuela. He was responsible for establishing the scientific basis for the teaching and practice of medicine in his country.

The award was presented to Dr. Barber recently at the annual reunion of the Venezuelan Society of Dermatology in Valencia which he attended as a guest lecturer.

In 1959, Dr. Farber and other Stanford faculty member helped plan a new curriculum at Central University that has become a model for medical education in Venezuela. In addition, many Venezuelan specialists in dermatology were trained at Stanford in recent years.

"Thanks to Dr. Farber, there is a permanent bond of cordiality, friendship and scientific solidarity between Stanford University and Central University of Venezuela," the citation read.

STANFORD -- A unique clinic to help patients whose normal toilet habits have been altered by major abdominal surgery has been opened by Stanford University Medical Center.

The purpose of the clinic is to rehabilitate patients of all ages to an independent existence so they can resume normal activities. Patients return to work, school, sports and other activities they enjoyed before their illness and surgery.

Each year some 70,000 people in the United States spend a few hours on the operating table and have their toilet habits of a lifetime swept away.

These patients have enterostomy surgery, often performed to provide another outlet for waste products when the intestinal or urinary tract is diseased. A portion of the large or small intestine is brought out through the abdominal wall and sewn to the skin with sutures to create a new opening (stoma).

Since this artificial opening does not have muscles that can be tightened or relaxed, patients no longer have voluntary control over their normal physiological functions. They generally wear a bag-like appliance over the opening to collect bowel contents or urine. The appliance may adhere directly to the skin around the opening or may be held in place by an elastic belt.

For most, such an operation is overwhelming and embarrassing. These patients need help and encouragement in adjusting, especially after they leave the security of the hospital, according to Stanford surgeons.

Take for example, a 54-year-old mother from San Mateo, one of the patients who has been treated at the clinic.

Ten years ago, doctors told her she had less than six months to live because of cancer. She was determined to prove them wrong. Nevertheless, the next nine and a half years she spent fighting cancer and complications of radiation treatment which had incapacitated her large bowel, were a nightmare.

The turning point for the patient came last December when she underwent enterostomy surgery at Stanford Medical Center. She generally wears a collecting pouch, but after nearly a decade of illness, she has resumed normal activities.

Another 26-year-old patient from Campbell had been in and out of hospitals for two years with intestinal problems. Medication was not helping and her activity had come to a standstill.

Then she came to Stanford for enterostomy surgery. As a result, she too wears an appliance to catch her intestinal wastes. However, she finds it does not interfere with any of the activities she has once again been able to enjoy.

The Stanford clinic, which is part of the surgery clinic, is under the direction of Drs. Harry Oberhelman, Jr. and Duncan Govan, surgery professors at Stanford School of Medicine. It is run by nurse specialist Rosemary Watt.

"More care is needed for ostomy patients, especially in the West," said Dr. Oberhelman. "It takes time and effort to work with them, and I don't think physicians have done an adequate job in the past," he commented.

-more-

A trained nurse specialist such as Mrs. Watt can spend time helping patients adapt, Dr. berheldman pointed out. He added that studies indicate patients who see a specialist have fewer postoperative complications after they leave the hospital. The Department of Surgery is currently studying an innovative role of the nurse in the enterostoma clinic under a one-year grant from the Division of Nursing, National Institutes of Health.

When the rectum or some of the large intestine (colon) is diseased, the affected part is removed, and a small portion of the remaining intestine is brought out through the abdominal wall to establish a new opening. This procedure is called colostomy. Common indications for colostomy include cancer of the rectum or large bowel, and inflammation or obstruction in the lower intestinal tract.

Most colostomies are permanent, but some are done as a temporary measure to allow healing of an infected bowel. Patients can often control their evacuation by periodic irrigation (giving an enema through the opening) so they do not always have to wear a collecting pouch.

If the entire colon is removed, part of the ileum, the longest and lowest portion of the small intestine, is brought out through the abdominal wall. The procedure is called an ileostomy. Debilitating inflammation of the colon due to ulcerative colitis or regional enteritis, also known as Crohn's disease, is the usual reason for an ileostomy.

In rare cases, an ileostomy may be temporary. Patients do not have the potential for bowel ntrol that colostomy patients have and they must wear an appliance all the time.

When it is necessary to divert urine from the bladder, a ureterostomy may be performed. The ureters, which carry urine from the kidneys to the bladder, are brought out through the abdominal wall to provide a new pathway for urine excretion. Another method is the ileal conduit, in which a portion of the ileum is used to bridge the gap from ureters to skin.

Urinary diversions are performed for cancer of the bladder, certain birth defects and other obstructions. The flow of urine through the new opening is continuous and an appliance must be worn constantly.

The Stanford clinic serves the entire Peninsula community. Patients learn how to manage their condition, use special equipment and regulate their diet according to their needs. Those operated on at Stanford are seen before their operation and throughout their hospital stay, as well as after discharge. Patients may be referred by other physicians in the area, or they may refer themselves.

The physician and nurse both play important roles in helping these patients to adapt after surgery, according to Dr. Oberhelman. Physicians constantly improve their surgical technique to eliminate many management problems. However, they may not have time to give their patients the kind of personal attention they require. A nurse specialist, on the other hand, can devote time exclusively to rehabilitation.

"Before Mrs. Watt worked at the clinic, patients in this area had no one to turn to for continuous advice when they left the hospital," said Dr. Oberhelman. "It is reassuring for both patients and doctors to know there is someone available to help answer questions and manage problems."

-more-

Rehabilitation is very individual, Mrs. Watt noted, and each person adjusts in his or her own way. "The clinic provides social and psychological counseling as well as physical care," she explained. "With proper care and management, patients can live a normal life," she added.

Dr. Oberhelman agrees that patients should not feel limited by this operation. "I wouldn't discourage anyone from an activity, but it is up to the individual to be careful," he cautioned. "Patients can play football, ski, travel, or do anything else they want. Generally the worst that can happen is that the appliance will come off," Dr. Oberhelman said.

He felt that a colostomy was the best way to put the 54-year-old patient back on her feet. The energetic mother and grandmother is busy repainting her house and looks forward to bicycle riding and volunteer work in the fall. Her husband and four sons are delighted at her renewed activity, and their only regret is that they do not see enough of her now that she is always on the go.

The patient from Campbell was hesitant about having an ileostomy operation. "The son of my parents' friends had an ileostomy about ten years ago. He had a lot of difficulty because no one bothered to give him any care after he left the hospital. Needless to say, I didn't look forward to the surgery," she said. Her favorite activities now include swimming and motorcycling.

Enterostomy is not the answer for everyone, Dr. Oberhelman pointed out. Some problems clear up without surgery. However, when enterostomy is recommended, it is reassuring for patients to know there are facilities in the area to help them successfully manage their problem.

The United Ostomy Association, an incorporated group of former patients, has chapters throughout the United States. These groups are especially effective for moral support. Nevertheless, they do not take the place of the nurse specialist who combines professional knowlege and training with individualized care, Dr. Oberhelman commented.

Mrs. Watt, holder of a master's degree in surgical nursing, is the only nurse specialist in Northern California who offers services solely for enterostomy patients.

As a ranking authority in available community services, she is a consultant to various Bay Area agencies. She also works with the Santa Clara Chapter of the American Cancer Society to train enterostoma visitors for the United Ostomy Association and teaches medical, surgical and nursing staffs at hospitals.

STANFORD--Dr. Thomas A. Stamey, professor of surgery and head of the division of urology at Stanford University School of Medicine, is author of a new book, Urinary Infections.

The 293-page book was published this month by The Williams and Wilson Company of Baltimore. Designed for students and clinicians, it meticulously describes modern techniques utilized in the diagnosis, investigation and treatment of urinary tract infections.

Based on the broad experience of the urology division at Stanford, the book covers laboratory methods and operating principles used in dealing with urinary infections among all age groups.

It also describes the successful technique for management of kidney stones developed at Stanford. After determination that the patient's urine is absolutely sterile, surgical removal of the kidney stones is followed by irrigation with a drug solution, Renacidin, while the sterile urine culture is maintained. This method has greatly reduced the recurrence rate of infection.

Dr. Stamey, who worked on the book for several years, is editor of Urology Digest, and a member of the editorial board of two other medical journals, Kidney and the Journal of Investigative Urology.

He is the author of one other book, Renovascular Hypertension, dealing with the methods of studying kidney conditions in man which lead to high blood pressure. He has also published numerous scientific papers.

Dr. Stamey was recently awarded the American Urological Association's Hugh Hampton Young Award for his work on the diagnosis and treatment of urinary infections. A member of the national scientific advisory board of the National Kidney Foundation, he was past chairman of the renal disease and urology training grants committee of the National Institutes of Health.

A 1948 graduate of Vanderbilt University, he received his M.D. from Johns Hopkins University School of Medicine in 1952. He served on the faculty at Johns Hopkins for three years before coming to Stanford in 1961, and was appointed to his present position in 1964.

STANFORD--A special room for patients extremely susceptible to infection will be installed at Stanford University Hospital with a gift from the Medical Center Auxiliary.

The volunteer organization has donated $25,000 to finance the Hospital's first laminar flow room which will be used for treatment and research. Announcement of the gift was made today by Auxiliary president Mary Bohler.

Laminar flow is a method of filtering and circulating air that has proved successful in industry when a dust free environment is necessary. Although hospitals have used laminar flow hoods in operating suites and laboratories, the concept of an entire patient room is recent, according to Dr. Eugene Dong, Jr., associate professor of cardiovascular surgery at the School of Medicine.

Studies in other institutions have indicated that laminar flow rooms may decrease infection in patients with some forms of leukemia, Dong said. He will investigate how effective such a room will be in preventing infection in heart transplant patients. Their resistance is very low because in order to avoid rejection of the new heart, they are given drugs to suppress the body's immunity. They will spend a month in the special room.

The room may also be used for leukemia patients, who are often treated with immunosuppressant drugs, and for severe burn patients, who are prone to infection because their natural skin barrier has been burned off, Dong explained.

A room in the Hospital's intensive care unit is being converted for the air flow system and is scheduled to be ready in October. Air in the room will be sucked up by floor ducts and then passed through a filtering system. The cleansed air will be recirculated into the room in smooth sheets from vents in the ceiling. It will blow straight down to the floor, and then along the floor to the return ducts, passing smoothly around any physical barrier. A patient or anyone else in the room, then, will be isolated in a pocket surrounded by a curtain of air.

If patients with low resistance are being infected by bacteria that live in their own bodies, the laminar flow room will not help, Dong noted. He pointed out, however, that evidence implies that the infections come from external sources and are carried in the air of the patient's environment. If this is so, Dong said, the room could help protect the patients.

"No one knows for sure how effective a laminar flow room is for patients, but we hope to find out from the one we are installing at Stanford," Dong said. "Considering the favorable evidence thus far, and the extra cost and difficulty when a patient develops an infection, the room is an attractive bet," he added.

The 1100 member Auxiliary has served the Medical Center since it opened in 1959. It raises money solely through the gift shop which it operates and staffs at the Hospital. ###

STANFORD--Howard J. Wooling, of East Palo Alto, has been appointed assistant director of Stanford University Hospital.

The appointment, which becomes effective August 1, was announced Wednesday (July 12) by Dr. Thomas A. Gonda, hospital director.

Wooling, 31, received his Masters degree in public health last month from the University of California at Berkeley. He served his administrative residency at the UC Hospitals and Clinics in San Francisco.

At Stanford, he will assume line administrative responsibilities for several patient care services.

A native of Pittsburgh, Pennsylvania, he received his B.A. degree in 1965 from Eastern Nazarene College in Wollaston, Massachusetts. Two years later he obtained a Masters degree in education from Boston College.

From 1967-70, Wooling worked as an orientation and mobility specialist in the blind center at Palo Alto Veterans Administration Hospital. During his last two years at the VA Hospital, he was supervisor of the orientation and mobility section.

The position of assistant director at Stanford has been vacant since Donald G. Utt was promoted to associate director two years ago.

STANFORD--Dr. Henry S. Kaplan, professor and chairman of the Department of Radiology at Stanford University School of Medicine, has been elected to the Institute of Medicine of the National Academy of Sciences.

Dr. Kaplan was one of 52 new members elected to the Institute, President John R. Hogness announced Tuesday (July 10). Formed last year, the Institute now has 159 members.

Noted for his pioneering studies in the biologic and biochemical effects of radiation, Dr. Kaplan discovered that the genetic material DNA (deoxyribonucleic acid) is the target molecule in the cell for radiation effects. He demonstrated that radiation exposure or chemicals can trigger a latent virus which induces leukemia in animals.

He is well-known for his adaption of the linear accelerator for medical purposes, and the development of effective radiotherapy techniques for the treatment of Hodgkin's Disease and other malignant lymphomas.

Dr. Kaplan was also recently elected to the National Academy of Sciences. Chairman of the Department of Radiology at Stanford since 1948, he will step down from his administrative responsibilities at the close of the current academic year.

Institute members are elected by a vote of current members. Election is based on major contributions the individual has made to the general field of health care. Total active membership will reach 400 in the next few years.

Four members of the Stanford faculty were elected to membership last year, including Dr. Robert A. Chase, professor and chairman of the Department of Surgery; Dr. David A. Hamburg, professor and chairman of the Department of Psychiatry; Dr. Donald Kennedy, professor and chairman of the Department of Biological Sciences; and Dr. Joshua Lederberg, professor and chairman of the Department of Genetics.

The purpose of the Institute of Medicine is to study the larger problems of medicine and health. It provides a setting for professionals to improve American medicine and the national framework of health services.

STANFORD--Carl P. Sheaffer, Stanford University Hospital's longest surviving heart transplant patient and the fourth longest surviving transplant recipient in the world, died early this morning (July 7) at the Palo Alto Veterans Administration Hospital.

The cause of death is undetermined at the present time, pending results of an autopsy which will be performed today.

Sheaffer, 57, survived over 44 months after receiving his transplanted heart on October 26, 1968.

He had recently been admitted to the VA Hospital for rehabilitation from a back injury suffered in an automobile accident.

In 1963, Sheaffer was forced to retire from work as a plumber in Winchester Bay, Oregon and give up even mildly strenuous activity because of disabling heart disease. Following his transplant, moved to nearby Mountain View, but returned to Oregon frequently for fishing and hunting expeditions. He also worked out often in a local health spa.

Sheaffer is survived by his wife of 39 years, Effie, and five children, three sons and two daughters.

Funeral arrangements have not been made at this time. Sixteen of the 45 heart transplant patients are living.

STANFORD -- A federal grant totalling $718,697 for the first year and projected at $2,112,000 for the next four years, has been awarded to the Department of Psychiatry of the Stanford University School of Medicine for clinical studies of alcoholism.

Funding of the grant was confirmed by letter Monday (Aug. 28) from the National Institute on Alcohol Abuse and Alcoholism of the Health Services and Mental Health Administration in Washington, D.C.

The grant will support 16 different studies, including established research at the Medical School, and several newer approaches to the study of alcoholism.

Project directors are Dr. David A. Hamburg, professor of psychiatry, and Dr. Bert S. Koppel, associate professor of psychiatry.

They said the research represents a major interdisciplinary effort in research and education on alcohol problems. They also stated that the ultimate clarification of such a complex disorder will depend on a broad base of scientific understanding.

"Investigators must search persistently for the relevance of newly emerging information on brain, behavior, and social environment," the psychiatrists said. "We believe complex interactions of psychosocial and biological processes will prove to be crucial in the understanding of alcoholism."

The study will cover not only psychiatry, but other disciplines including genetics, pharmacology, biochemistry and neurophysiology.

One study, carried out by Dr. Elizabeth Bing, involves causes of mental health problems in children of alcoholic parents.

Another study by Dr. Irvin D. Yalom will involve Alcoholics Anonymous in evaluating group therapy approaches to the treatment of alcoholics.

Other projects will focus on understanding factors involved in alcohol use and abuse with emphas on young people, biological aspects, community environments believed to influence the malady, and the relationship of alcoholism to violence. The latter study will be carried out by Dr. Keith H. Brodie using the Medical School's newly established Laboratory of Stress and Conflict. ### Business Wire 8/29/72

Editors: Photos available upon request.

STANFORD -- Residents of a low-income section of San Jose have established a health center for the area's 20,000 residents with the assistance of Stanford medical students and California Regional Medical Programs.

The Gardner Community Health Center opened its doors June 28 in an old rectory at 325 Willow Street in San Jose. Since then, an average of 20 patients have been seen each Monday and Thursday night between the hours of 6:30 and 10:30.

Using donated medical supplies, equipment and drugs, the volunteer medical staff provides primary and emergency care to the residents of the Gardner district, a largely Chicano area in western San Jose.

For many years, the Gardner area has been medically indigent, cut off from the health facilities in San Jose by a lack of public and private transportation, low incomes, and in many cases a language barrier, said Roberta Horoho, a public health nurse from Regional Medical Programs (RMP) Area III office at Stanford, who serves as medical coordinator of the center.

"Many of the people here have had no medical care at all, while others have had little or fragmented care," she said. "Many speak little or no English, and if they could get to one of the area's health facilities, would have trouble communicating their needs."

In response to those needs, a clinic was opened in July of 1971 through the combined efforts of a group of Stanford medical students led by fourth-year student Chris Murias, San Jose Model Cities, and RMP. But plagued by lack of funds and facilities, it closed its doors in November.

In the wake of that short-lived clinic, representatives of several civic groups in Gardner established a community board of directors to organize a new clinic, guide its operations, and set its policies.

"After the first clinic closed, we decided that the only way we'd get our clinic was to do it ourselves," said Jim Flores, board chairman and chairman of the Gardner Neighborhood Council. "Community members had to be the ones to provide the organization and support."

The board--composed of seven delegates from local organizations, a physician from the Santa Clara County Medical Society, and a private dentist (future plans call for a dental clinic)--incorporated the health center as a non-profit organization in December. A few months later, a malpractice insurance policy and a license from the California Department of Public Health were obtained.

In February, the board leased the old rectory, located adjacent to Sacred Heart Church, from the church for $1 (one dollar) per year. Renovation was begun in May by a group of volunteers consisting of community members, Stanford medical students, and students from other local colleges.

-more-

The volunteers spent $650 on the preliminary renovation. Money was raised from raffles, dances, and private donations, including one of $100 from the Stanford Medical Student Association.

"Working over a period of eight weekends, we changed the first floor from a five-room residence to a 10-room medical clinic," said Mike Kirkpatrick, administrative coordinator of the clinic. (Kirkpatrick began working at Gardner as a volunteer; his position is now funded by the Office of Economic Opportunity's Economic and Social Opportunity Community Action Program, and by RMP.)

The clinic now includes five examining rooms, an office, waiting room, laboratory, physicians' consulting room, and wash room.

It operates on an appointment basis, except in emergency cases. Medical services are presently free, although in the future a "pay if you can" billing system may be established, Kirkpatrick said.

In addition to Monday and Thursday evenings, the clinic has performed contract physical exams for the Neighborhood Youth Corps this summer on Thursday afternoons. Additionally, the Santa Clara County Department of Public Health operates a well-baby clinic Wednesday afternoons.

Equipment and supplies have been donated by over 25 organizations, including Stanford and Santa Clara Valley Medical Centers, O'Connor Hospital, pharmaceutical firms, private laboratories, local physicians and nurses.

Medical care is provided by a volunteer staff consisting of residents and interns from Stanford Hospital, private physicians, fourth- and fifth-year Stanford medical students, and nursing students from Stanford and California State University at San Jose.

Technologists from Stanford Hospital and pre-med students from San Jose man the laboratory. Community members have volunteered their services as secretaries, receptionists, and translators.

For Stanford, the initial tie to Gardner was made when Murlas, fourth-year medical student from Chicago, became interested in the health care problems of the area and led the organizing and recruitment efforts which culminated in the first clinic. Murlas has continued his active involvement in the new health center.

Despite the success at Gardner, problems remain, mostly related to future financing.

"Our biggest problem is finding operational money," Kirkpatrick said. "To date the clinic has only received assorted small grants for renovation of the rectory and drug education and abuse programs. But we've received no operational funds."

The clinic is now applying to RMP and the Campaign for Human Development for this funding. Sustaining support from government grants, foundations, and private donations will be needed, Mrs. Horoho said, because the clinic is located in a poverty area.

"I think it's unrealistic to expect that a center like Gardner can ever totally support itself," she said. "The people here just don't have the money."

-more-

The clinic serves a six square mile area in San Jose. About two-thirds of the population of 20,000 is Chicano. Gardner residents generally have little education, poor housing, poor nutrition, and many are without jobs, Mrs. Horoho said. Nearly one-fourth of the community receives welfare of some sort, and 25 per cent have a family income under $4,000, she added.

For these people, the clinic represents the fulfillment of a dream for a community-operated and controlled health clinic, Flores said.

For the students from Stanford and other local campuses who have volunteered their efforts, the satisfaction has been of a different nature.

"The students who work here receive no monetary or academic rewards," said Murlas. "We get no course credit and no stipends--just the satisfaction of helping these people get decent health care."

In all, approximately 30 Stanford medical students have volunteered their services at Gardner. In addition to Murlas, three other students have been involved in the organization and planning of the center--Fernando Mendoza, second year, San Jose; Larry Crapo, fifth year, Santa Barbara; and Scott Brassfield, third year, Tulsa. Fred Krefetz, Stanford business student from Coral Gables, Florida, has assisted Kirkpatrick in administration of the clinic.

RMP's Area III office at Stanford, in addition to assigning Mrs. Horoho to Gardner as health coordinator on nearly a full-time basis, has provided stipends for two students to work at Gardner for the past two summers. Also, RMP area coordinator Dr. William Fowkes has volunteered medical and administrative time to the center.

STANFORD -- Dr. David A. Hamburg, professor and chairman of the Department of Psychiatry at Stanford University School of Medicine for the past 11 years, will step down from his administrative responsibilities on October 1 to pursue new programs of education and research.

His resignation was announced today (August 28) by Dean Clayton Rich. Dr. Rich said he accepted the resignation "with real regret" and praised Dr. Hamburg's "tremendous contribution to the school and to the discipline of psychiatry."

The dean said he plans to appoint a search committee to aid in the selection of a successor.

Dr. Hamburg stressed his desire to pursue three new programs of education and research he has been instrumental in developing--the Laboratory of Stress and Conflict and the Human Biology Program, both at Stanford; and the Program on Science, Technology, and Society at the Center for Advanced Study in the Behavioral Sciences, located in the foothills behind the Stanford campus.

The Laboratory of Stress and Conflict is an interdisciplinary faculty project organized by Dr. Hamburg to develop courses and research projects on behavior under stress. It involves work with patients and also research on chimpanzees at the forthcoming Stanford Primate Facility and in Africa.

The Human Biology Program is a recently developed undergraduate major at Stanford, in which faculty members from the medical school and the biological and social sciences team to present a comprehensive view of man from a life sciences perspective. Dr. Hamburg was one of the program founders.

He also aided in the planning of the Program on Science, Technology, and Society, in which a group of scholars will come to the Center for Advanced Study in the Behavioral Sciences each year to study the social impact of scientific and technological developments.

-more-

Dr. Hamburg, 46, came to Stanford in 1961 from the National Institutes of Health, where he was chief of the Adult Psychiatry Branch. Under his leadership, the Department of Psychiatry has earned international recognition, particularly for its scientific approach to psychiatric problems.

* * * * * *

EDITORS: Additional background on Dr. Hamburg follows.

A 1947 graduate of the Indiana University School of Medicine, Dr. Hamburg received his professional training at Michael Reese Hospital in Chicago and Yale University.

His research has focused on hormonal responses to psychological stress, ways in which individuals cope with very difficult circumstances, and conflict resolution.

The author of nearly 100 papers, Dr. Hamburg has served on the editorial boards of 10 medical and scientific journals. He recently published a book, Psychiatry as a Behavioral Science, and has edited two others.

He has been elected to membership in the American Academy of Arts and Sciences, and the National Academy of Sciences' Institute of Medicine. Past chairman of several boards and committees of the major professional psychiatric organizations, he has served on the executive committee on behavioral sciences of the National Research Council.

He has also served as president of the Association for Research in Nervous and Mental Disease, and chairman of the Psychiatric Research Society.

STANFORD -- Dr. Malcolm A. Bagshaw, professor and director of the division of radiation therapy, has been appointed chairman of the Department of Radiology at Stanford University School of Medicine.

His appointment, which is effective September 1, was announced today (August 22) by Dean Clayton Rich.

Dr. Bagshaw succeeds Dr. Henry S. Kaplan, chairman of the department for 23 years, who resigned to devote himself more fully to teaching and research activities.

Director of radiation therapy at Stanford since 1960, Dr. Bagshaw is noted for his pioneering efforts in the treatment of cancers of the prostate and the larynx. He has done extensive research on the treatment of localized human cancers with a combination of drugs and intensive radiation therapy.

During the past two years he has been involved in the investigation of a new weapon against cancer, beams of sub-atomic particles called pi mesons or pions. Radiotherapists believe that pion radiation, which may be ready for clinical use in two to three years, could be much more effective than conventional radiation therapy.

A 1950 graduate of Yale University School of Medicine, the 47-year-old radiotherapist received his professional training at Yale and the University of Michigan.

He joined the staff at Stanford in 1956 as instructor in radiology and was made assistant professor three years later. He advanced to associate professor in 1962, and was appointed a full professor in 1969. For the past 11 years he has been assistant director of Stanford's Clinical Radiotherapy Cancer Research Center, supported by the National Cancer Institute.

Dr. Bagshaw is a member of the major professional societies and former chairman of the American Cancer Society's National Advisory Committee for Research. Past chairman of the National Institutes of Health (NIH) Radiation Study Section, and a former member of the executive committee of the Association of University Radiologists, he is president-elect of the American Association of Therapeutic Radiologists.

The author of over 70 publications, most dealing with radiation therapy and human tumors, he is a member of the editorial board of Investigative Radiology.

STANFORD -- Scientists at Stanford University School of Medicine believe they have found a chemical co-factor which induces crises in patients with sickle cell anemia.

Sickle cell anemia is a potentially disabling hereditary blood disease which almost exclusively affects black people. In a crisis, which can last for several days or weeks, the victim suffers excruciating pain and is frequently disabled.

The Stanford investigators discovered that sickle cell crises may be initiated or enhanced by one of the prostaglandins, fatty acids manufactured in many tissues of the body and capable of acting in various ways on most body tissues in very minute quantities.

Prostaglandins have been used in clinical trials in the United States, Sweden, and other countries to induce labor and abortion, and to treat asthmatics.

With this discovery, scientists may now attempt to find drugs which will inhibit production of the prostaglandin type that causes sickle cell crises.

The findings were reported today (August 22) at the meeting of the American Association of Clinical Chemists in Cincinnati, Ohio, by the Stanford researchers--Dr. Paul L. Wolf, associate professor of pathology and director of clinical laboratories; and biochemists Drs. Israel Rabinowitz, Malcolm Johnson, and A. L. Willis.

The work was supported in part by a $92,000 grant from the National Heart and Lung Institute to Dr. Wolf and Dr. Linus Pauling, Stanford's Nobel Prize-winning chemist who did much of the early research on the molecular basis for red blood cell sickling.

The red blood cells of sickle cell anemia victims become elongated, shaped like crescents or sickles. Unlike normal round red blood cells, they have difficulty moving through the body's smaller blood vessels.

The result is seriously impeded blood flow and reduced oxygen supply to various body tissues, causing severe pain, increased infection, and often malfunction of body organs and disability.

Approximately 50,000 American blacks have sickle cell anemia. Another two and a half million carry the gene for the disorder and have sickle cell trait, though they usually do not suffer the symptoms of the disease.

For several years scientists have been searching for chemical co-factors which may trigger sickle cell crises. The Stanford researchers believe that prostaglandin may represent such a co-factor.

In tests they conducted during the past eight months, small concentrations of the prostaglandin known as E_2 were added to the red blood cells of sickle cell anemia patients.

"We found that the prostaglandin induced increased sickling in the red cells of the sickle cell anemia victims," Wolf said. "On the other hand, no changes were observed when it was added to normal cells."

-more-

To verify that sickling had occurred, urea (known to be capable of reversing the process) was added to the solution and the sickling was reversed. Changes were observed by light scattering and spectrophotometry.

The next step in this research, Wolf said, is to attempt to find drugs, perhaps prostaglandin analogues or antagonists, that can aid in the treatment of sickle cell anemia by inhibiting the prostaglandin type which causes sickling.

The Stanford investigators began to study prostaglandins, Wolf said, when it became apparent that "certain symptoms of sickle cell crises, such as inflammation and fever, simulated symptoms which can be induced by prostaglandin injections."

Additionally, Rabinowitz noted, levels of prostaglandins in body tissues are elevated during or following infection and during pregnancy. These events are associated with increased incidence of sickle cell crises.

Scientists had also demonstrated that prostaglandin made red cells more rigid, so they wouldn't fit through the finer blood vessels, Johnson said. "This, plus our own preliminary results, gave us both direct and indirect evidence that it might affect the red blood cells of sickle cell anemia patients," he concluded.

Blood samples for the tests were obtained through the assistance of local sickle cell anemia foundations, notably Sickle Cell Anemia Research and Education (SCARE) of San Francisco-Oakland.

STANFORD -- A 47-year-old California man became the 47th heart transplant recipient at Stanford University Hospital late last night (August 20). He is now listed in satisfactory condition.

A team of surgeons headed by Dr. Norman E. Shumway performed the operation.

Both the recipient and the family of the donor requested anonymity.

The operation was the second performed by Dr. Shumway and his team within four days. On August 17, a 26-year-old Midwestern man received a transplanted heart. He is now in satisfactory condition.

Including the new recipient, 17 of Stanford's 47 heart transplant patients are now living.

STANFORD -- A 26-year-old Midwestern man became the 46th heart transplant recipient at Stanford University Hospital yesterday afternoon (August 17). He is now listed in fair condition.

A team of surgeons headed by Dr. Norman E. Shumway performed the operation.

The patient, who requested anonymity, is the second youngest ever to receive a transplanted heart at Stanford. The youngest, a 19-year-old man from Texas, is in good condition and was recently released from the Hospital.

Including the new patient, 16 of Stanford's 46 heart transplant recipients are now living.

ADVANCE FOR A.M. RELEASE, THURSDAY, AUGUST 10, 1972

STANFORD -- Stanford Medical School's long-awaited training program for physician's assistants was launched this month, with the support of two federal grants totalling $360,226.

Forty students will receive training in the project, supported by the one-year contracts from the Bureau of Health Manpower of the Department of Health, Education and Welfare, and the California Regional Medical Programs.

Most of the funds will be spent for instruction, but some will go for student stipends, and evaluation of the initial phase of the training program.

The purpose of training physician's assistants is to improve the distribution of health professionals and the delivery of primary care, especially in poorly served inner-city and rural areas. Such assistants will free a physician to focus his skills where they are most needed.

The contracts, among several in the nation to be awarded for the training of physician's assistants for primary care, were announced today (Aug. 10, 1972) in Washington, D.C.

In 1970, California became one of 23 states which explicitly authorized the activities of M.D. assistants. Since then the State Board of Medical Examiners has been wrestling with the issues of developing an appropriate training model for California, setting up standards and legal requirements, and resolving problems of future employment of these new paraprofessionals.

The Stanford program and another co-sponsored by the University of California in Los Angeles and Charles Drew Medical Center in Watts, are the first programs to begin in California since the state enabling law was passed.

Stanford's program represents a four-year commitment. According to Dr. Michael T. B. Dennis, program director, this initial phase will lay the framework for future M.D. assistant training programs at Stanford. One area of anticipated expansion is training assistants in emergency care services.

Pointing out that training of physician's assistants varies widely, Dennis is cautious of developing programs which encourage early specialization of physician's assistants in fields such as surgery, psychiatry, or radiology where there are not yet validated needs.

"These programs ignore the identified needs for primary care in rural and inner-city areas," Dennis said.

Stanford's physician's assistant training is a two-year curriculum run jointly with Foothill College. It leads to an Associate of Science degree, and certification through a state-wide examination. All courses taught at Stanford and Foothill will carry academic credit.

A high school diploma or equivalent is required to enter the program. Students with an associate of science or higher degree can be admitted with advanced standing. -more-

"The program has been designed to attract men and women with varied backgrounds," Dennis emphasized. "It would include former military corpsmen, registered nurses, and persons with scientific backgrounds."

There is a special effort, Dennis continued, to recruit members of disadvantaged or minority groups, women or residents of medically underserved areas.

The present physician's assistants class of 20 includes nine former army medics and six registered nurses. Five students are members of minority groups, with previous medical experience or patient contacts. Another class of 20 will soon be accepted, bringing the total to 40 students.

"One of the objectives of the Stanford program will be to place 80 per cent of its graduates with physicians in areas where medical services are needed," Dennis said.

These men and women will engage in supervised medical practice. They will be trained to do many things for many patients--take medical histories, perform diagnostic workups, suture minor wounds, make rounds in extended care facilities, counsel in preventive medicine, and participate in the management of chronic disease.

Getting accepted into the Stanford program is not a matter of just applying. "For the class that just began, we had more than 1,430 applications," Dennis explained.

The application form asks for detailed educational background and medical experience. The applicant must attach a one-page narrative on why he wants to be a physician's assistant.

In addition, evaluation forms must be completed by a physician with whom the applicant has worked, his present supervisor, and a personal acquaintance of five years or more. Transcripts of all grades from high school on up are also required.

In the first part of their two-year study, the physician's assistant trainees cover such areas as anatomy, physiology, psychology, biology, the philosophy of primary care, anthropology, English, algebra, and other requirements of the junior college degree. This program is carried out at Foothill College.

In their second year, the trainees are taught medical history taking, general theory and practical knowledge relating to common medical problems in primary care for 17 weeks. The students then rotate through inpatient and outpatient services at Stanford Medical Center and neighborhood health clinics for 18 weeks. They are exposed to general medicine, community medicine and public health, obstetrics and gynecology, pediatrics, psychiatry and surgery.

Completing the second year, the student spends 12 weeks with a practicing doctor in a community. There is a minimum of a one-year residency in the program.

Before launching its program, Stanford did careful spadework with local leaders in the health field. Among other things, it surveyed 1,640 doctors throughout the state to get their reactions to physician's assistants. There were 700 replies to the survey, and 235 physicians indicated a strong interest in hiring an assistant. Most of these doctors were in rural or inner-city areas.

Subsequently, many of these doctors were interviewed with respect to the job they envisioned such paramedics to be doing, and the kind of diseases they encountered in their daily practice. This information was used in the design of the curriculum. ###

STANFORD--Dr. Boris V. Petrovsky, minister of health of the U.S.S.R., Friday (Aug. 4) will visit the Stanford University Medical Center as part of a four-day tour of health facilities in California.

Dr. Petrovsky is visiting the United States on the invitation of the U.S. Secretary of Health, Education and Welfare Elliot L. Richardson in keeping with the purposes of the recent U.S.--U.S.S.R. joint agreement on health cooperation.

The 64-year-old health minister is scheduled to arrive in San Francisco Thursday (Aug. 3) and will visit the Kaiser Permanente Medical Center in Oakland.

He is accompanied by, his wife (Madame Ekaterina M. Timofeeve, also a physician) and four other Russian officials.

At Stanford, Dr. Petrovsky will confer with Dean Clayton Rich of the School of Medicine, Dr. Thomas A. Gonda, hospital director, Dr. Norman E. Shumway, heart transplant pioneer, and Dr. Donald Harrison, chief of cardiology.

Dr. Petrovsky is a surgeon, and specializes in thoracic surgery and treatment of congenital and acquired heart defects. He is also director of the Scientific Research Institute of Experimental and Clinical Surgery.

The Russian officials will attend a luncheon with Stanford University President Richard W. Lyman at the faculty club.

In the afternoon, Dr. Petrovsky and his entourage plan to visit the Alviso Family Health Center, 1621 Gold Street, in Alviso.

Dr. Petrovsky will visit Los Angeles, and Atlanta before returning to Washington, D.C.

STANFORD -- In a detailed study to determine how industrial oil affects birds, a Stanford University medical research team found that birds exposed to oil spilled in the San Francisco Bay last year died from ingesting large amounts of oil or from infections and stress related to their exposure and handling.

The birds had been brought to the San Francisco Zoological Gardens for cleaning and care.

The findings, by veterinarian Jim Fox and Steven Snyder of the Medical School's Division of Laboratory Animal Medicine, were presented recently to the Environmental Protection Agency in San Francisco and the Wildlife Disease Conference at Ann Arbor, Michigan.

The work was supported by a grant from the Standard Oil Company, whose Arizona Standard and Oregon Standard oil tankers collided in the San Francisco Bay January 18, 1971. Some 840,000 gallons of bunker c fuel -- a crude oil -- were spilled, contaminating the Bay and 110 miles of the California coastline, from Point Reyes to Santa Cruz.

A better understanding of the pathological effect of oil contamination on waterfowl may lead to improved methods of treating exposed birds and help assess the dangers to breeding affected populations, the researchers believe. They also feel it will aid in evaluating the overall impact of oil pollution on the environment.

"Our pathological findings imply that bunker c oil is toxic to tissues and organs of exposed waterfowl and can be a contributing factor to the deaths of debilitated birds," they reported.

"Birds that spend much of their time on the water are most susceptible to oil contamination," explained Fox, "for they swallow and ingest oil while cleaning their feathers." The three species particularly affected by the Bay oil spill were the western grebe, common murre and surf scoter.

In the 3-1/2 months following the spill, the Stanford investigators examined tissues and organs of 119 birds that had died after being brought to the San Francisco Zoo for cleaning. Specimens from the dead birds were analyzed, using standard histochemical and microbiological techniques, for pathological changes and chemical residues that could be attributed to the oil.

-more-

The birds were selected from the 1,600 received by the Zoo to represent the geographical range of the spill, common species affected, and different time intervals from exposure to death. Ten more birds that had not been exposed to oil served as controls and were examined in the same manner.

Mortality was highest during the first two weeks after the oil spill, and by the end of the second week, 90 per cent of the birds housed at the Zoo had died.

The gastrointestinal tract of these animals revealed the presence of oil; the intestines were often filled with a "black tarry substance" or contained "scattered clumps of oil," the researchers observed. Liver and kidney damage from the fuel chemicals and lung congestion were also widespread in this period.

As the time in captivity lengthened, oil was rarely seen in the intestines, and the incidence of oil toxicity in the liver, kidney and lungs decreased. However, there was an increase in infectious diseases and in degenerative changes in tissues.

By the end of the study, less than two per cent of the birds brought to the Zoo were still alive, Fox noted.

He emphasized that any evaluation of oil contamination to birds should take into account several factors -- chemical composition of different oils, amount of weathering on the sea, extent and length of exposure to oil and the degree of starvation, heat loss, handling or other stresses to the bird.

ADVANCE FOR P.M. RELEASE ON THURSDAY, SEPTEMBER 28.

STANFORD -- Discovery of a new drug which prevents rejection of transplanted kidneys in rats, apparently without affecting their immune mechanism against infection, was reported today (September 28) by a Stanford medical student working with the University's heart transplant team.

The new drug is chicken serum, harvested from a bird after it has been immunized with cells from the rat transplant donor.

If the drug is proven effective in other mammalian systems and then in humans, it could provide a long sought-after immunological key to more successful organ transplantation.

Randall E. Morris, a fourth-year Stanford medical student, found that the chicken serum significantly prolonged the survival of rats receiving kidney transplants in recent experiments at the Medical School.

Morris reported the research today at the Fourth International Congress of the Transplantation Society in San Francisco. Co-authors of the report included Drs. Eugene Dong, Jr., K. Enomoto, and heart transplant pioneer Norman E. Shumway, and Stanford premedical student Gregory Kay.

The investigators hope to test the serum in human transplant patients a year from now, if the preliminary results in rats are corroborated by further studies in other mammals.

Rejection and destruction of transplanted organs by the recipient's immune system has posed the main obstacle to successful human organ transplantation and forced almost all heart transplant teams to give up their efforts. For several years, scientists have been searching for an immunosuppressive agent which prevents rejection, yet does not cripple the body's defenses against infection.

In an interview, Dr. Dong, associate professor of surgery and senior author of the report, said:

"We've found that by using this chicken serum in rats, we're able to prevent rejection of the kidney graft and extend the survival of the recipient very significantly. On the basis of continuing experiments, we believe that this serum does not adversely affect the recipient's immune system."

Thus, unlike other immunosuppressive drugs, the serum may not check the body's defense mechanism and leave the recipient vulnerable to increased infection, Dong said.

Presently, organ transplant rejection is usually treated with horse serum, known as anti-lymphocyte globulin. (Lymphocytes are white blood cells, part of the body's immune system. Globulin is a fraction of blood plasma made up of proteins and containing protective substances called antibodies.)

Horse serum, Dong explained, is directed against human white cells. The serum attempts to keep the recipient's immune system, which recognizes the transplanted organ as foreign material, from rejecting and destroying it. But suppressing the white cells can leave the patient without adequate defenses against infection.

-more-

Chicken Serum Prevents Rejection

The horse serum kills the white cells by activating a destructive enzyme system known as complement, Dong said. In contrast, the chicken antibodies, due to their unique molecular structure, do not activate this enzyme system.

More importantly, he added, the chicken antibodies apparently protect the transplanted organ from the recipient's immune system by reacting with the donor organ cells in a non-damaging way.

The experiments were conducted at Stanford over the past several months in two groups of rats. Morris found that "none of the rats who received the serum from immunized chickens following kidney transplants died of rejection."

In the first group, four white rats received kidneys from inbred, but unrelated brown rats. Two received the chicken serum and two served as controls.

The normal survival time for unrelated rats receiving kidney transplants is approximately 10 days. Both control rats died on day 11 due to rejection. One experimental rat is still living after 42 days with good kidney function. The other died after 15 days of causes unrelated to rejection with a functioning kidney.

In the second group, eight white rats received kidneys from related brown-white rats. This is similar to a kidney transplant within a family in humans. Three rats served as controls and five [illegible]ived the treatment serum.

One of the controls died at 10 days due to rejection; the others are still alive past 25 days. All five experimental rats survived past 20 days. One is still alive after 150 days, and two are alive past 40 days. The other two died of surgical complications on days 25 and 35.

Morris' procedure in the experiments was as follows:

White blood cells from the rat donor were injected into a rooster several times to build up his antibody level. After a period of three weeks, the rooster's blood was harvested.

Red and white blood cells were removed from the blood, and the globulin was precipitated out from the serum.

Then the kidney transplant was performed. The chicken serum was administered intravenously immediately after the transplant and periodically throughout the following two weeks.

In the cases of the controls, serum from non-immunized chickens was used.

Morris, 24, from Hillsborough, has been working under Dong's preceptorship as part of Stanford's Medical Scientist's Training Program, supported by the National Institutes of Health.

In addition to Morris and Kay, three other Stanford students contributed to the experiments--medical student Edward So, and pre-med students Molly Cooke and Charlene Struthers.

STANFORD -- A new, simple operation to restore urine control without major surgery to women who suffer from incontinence is being done at Stanford University Hospital. The technique eliminates the need for abdominal or pelvic surgery.

Dr. Thomas Stamey, professor of surgery and head of the Division of Urology at Stanford School of Medicine, devised the procedure. He presented the results in 16 patients over the past two years at a recent meeting of the Western Section of the American Urological Association in Vancouver, B.C.

Women who have borne children or are over 40 often experience urine incontinence, particularly during strenuous activity. They may wear rubber pants or pads to absorb any wetness.

To cure the condition, Stamey has devised a reliable method of tightening the urinary bladder (where urine is stored) with a suture on either side. He uses a cystoscope, an instrument for examining the bladder, to accurately place the sutures with special needles he designed.

"The operation has been 90 per cent successful," Stamey noted, "with all patients cured or markedly improved."

Stamey's method is a major modification of a similar operation developed by A. J. Pereyra, a California gynecologist. Pereyra initially showed the feasibility of drawing a suture through a special needle from the abdominal wall to the vagina. "He does not use a cystoscope, however, so he cannot see exactly where he is putting his sutures," explained Stamey.

Although the procedure is designed for females, its principles can be applied to male patients. Men, however, only need such an operation when the muscle that controls the flow of urine has been injured.

Women, on the other hand, can develop an inability to control urine without any apparent injury. It usually begins as occasional loss of bladder control during a strenuous activity. This condition, known as stress incontinence, generally worsens gradually and can result in total incontinence. Pregnancy and childbirth, which put considerable strain on the bladder, account for much of the incidence in females, but even women who have never been pregnant develop stress incontinence, according to Stamey.

With his technique, Stamey inserts the cystoscope in the urethra (the canal which discharges urine from the bladder) to observe that he places the sutures accurately. The sutures should be put exactly at the junction of the bladder and urethra, one on either side. There, they pull up the bladder and make it strong enough to hold urine without any leakage. For the suturing, Stamey developed three special needles with varying angles, which the Pilling Company of Pennsylvania made for him.

A total of 25 women, ranging in age from 15 to 88, have now been operated on at Stanford. comfort is minimal and most patients go home three or four days after their surgery, reported Stamey.

He added the procedure can even be performed on patients who have extensive scar tissue from previous surgical attempts to correct their condition.

STANFORD -- The world's most powerful nuclear magnetic resonance spectrometer to study the mysteries of tiny atoms that make up a biological molecule will be built at Stanford University.

Funded by a $500,000 federal grant, the spectrometer will be part of a highly sophisticated instrumentation center to aid scientists in their efforts to understand and conquer disease.

The funding of the facility will be evenly split over the first three years of operation by the National Science Foundation and the National Institutes of Health.

Under the terms of the grant, the facility, scheduled for completion within a year, will serve as a regional resource in the San Francisco Bay Area. It will be used by eminent chemical physicists, physical chemists, biochemists, and pharmacologists from Stanford, the University of California, San Jose State University, and other area institutions.

In a joint statement, the two federal agencies said the project would assist in the solution of significant chemical, biochemical, and pharmacological problems. It would provide training for qualified scientists, and encourage the application of high-frequency, high-resolution nuclear magnetic resonance to chemistry, medicine and biology on a wider scale.

A nuclear magnetic resonance spectrometer makes it possible for researchers to observe the magnetic properties of atoms in a molecule, by providing information which describes their spacial relationships.

The technique allows scientists to "look" at structures many times smaller than can be seen with an electron microscope. In addition, it does not cause chemical alterations on the object being observed and can follow events in time.

For instance, a scientist may label amino acids (the building blocks of proteins) with stable isotopes and can chart changes in protein structure, which is important in understanding disease.

The scientists will study mechanisms of genetic control, cell membranes, drugs and their effect on enzymes, and the geometry of protein molecules. Abnormally shaped proteins have been associated with hereditary diseases.

The new facility will be directed by a committee chaired by Dr. Oleg Jardetzky, professor of pharmacology. Members are Dr. Harden M. McConnell, professor of chemistry; and Dr. Calvin F. Quate, professor of applied physics.

"Stanford's nuclear resonance spectrometer will approach a resolution of 360 MHz (Mega Herz), Dr. Jardetzky said. "We are confident that such a high resolution instrument can be built by available technology."

(At present, the world's most powerful nuclear resonance spectrometer is at the California Institute of Technology. It was made by Varian Associates and approaches a resolution of 300 MHz).

The spectroscopic technique was developed at Stanford 25 years ago by Nobel Laureate Felix Bloch, emeritus professor of physics. Other Stanford scientists who played a leading role in the development of applications of the method to chemistry and biochemistry are Professors McConnell and John D. Baldeschwieler, chemistry; and Dr. Jardetzky.

STANFORD -- Dr. David Glick, professor of pathology at Stanford University School of Medicine, was elected president of the International Committee for Histochemistry and Cytochemistry.

The election was held at the Fourth International Congress of Histochemistry and Cytochemistry, held recently in Kyoto, Japan.

Dr. Glick, a specialist in tissue chemistry, has contributed to the development of methods for analysing the chemical composition of cells and tissues in the body, and to their application in biomedical research. These methods employ a variety of techniques, such as microchemistry x-ray absorption, electron microscopy and laser spectroscopy.

The International Committee, made up of the presidents and secretaries of every national histochemical society, in addition to the president and a secretary-general, is responsible for coordinating the international congresses and other world activities of the national groups. Dr. Glick served twice as president of the United States Histochemical Society.

Author of some 250 research papers and several textbooks (one of which has been translated in the Soviet Union), Dr. Glick is co-editor of a new review series, Techniques of Biochemical and Biophysical Morphology, whose first volume is scheduled to appear next year. He is also editor of the 21 volumes of Methods of Biochemical Analysis, started in 1954.

In 1932, Dr. Glick received a Ph.D. degree in biochemistry from the University of Pittsburgh. Subsequently he worked in Scotland, Italy, Sweden and Denmark, and is a member of the Royal Danish Academy of Sciences and Letters.

Before joining the Stanford faculty in 1961, Dr. Glick served on the faculty of the University of Minnesota Medical School for 15 years. Since 1962, he has been recipient of a Public Health Service Career Award from the National Institute of Arthritis and Metabolic Diseases.

STANFORD -- Lead arsenate, a widely-used insecticide, does not pose a serious threat to the health of seasonal sprayers, according to an independent study by a Stanford University pharmacologist.

"The use of lead arsenate spray for ornamental plants is not an acute health hazard for the seasonal sprayer in normal health," said Dr. Sumner Kalman, professor of pharmacology at Stanford Medical School. "This is most likely due to the seasonal and brief nature of the exposure."

Kalman conducted a survey of a group of lead arsenate sprayers and their co-workers in Santa Clara and San Mateo Counties during the spring of 1971. He reported his findings recently in a report to the California Department of Public Health's Bureau of Occupational Health and Environmental Epidemiology.

Lead arsenate sprays and dusts have been used in orchards and cotton fields in this country for over 75 years. In the group Kalman studied, the spray was used for four weeks in April and May of 1971 to control the oak moth caterpillar, especially to protect ornamental plants.

Forty-five sprayers, tree surgeons, mechanics, supervisors, brush clearers and office personnel were included in the survey. Urine samples and hair samples were analyzed to determine lead and arsenic concentration and to check for possible poisoning.

"There was no evidence of toxicity," Kalman said. "None of the subjects appeared to have clinical signs of lead or arsenic poisoning."

Urinary lead levels were within the normal to high normal range, and there was no clear-cut difference between the mean lead concentration for sprayers and non-sprayers, he added.

Kalman pointed out, however, that lead arsenate can be toxic to individuals exposed over a long period of time, as reported in a U.S. Public Health Service study of workers in the apple orchards of Washington 30 years ago.

"Use of this insecticide should be avoided, since both lead and arsenic are persistent substances," he stressed. "It will probably be phased out, primarily because it contaminates the soil."

Kalman's survey was conducted independently, without any supporting funds. Lead toxicity studies were performed in Stanford's Department of Chemistry by Drs. Carl Djerassi, Ed Bunnenberg and Gunther Barth, using a new method of urine analysis which requires a very small sample. Professor Thomas Connolly of Stanford's Ryan Laboratories used highly sensitive analysis of hair to determine arsenic contamination.

The study was done in cooperation with S. P. McClenahan Pest Control Company of Palo Alto.

STANFORD -- A scholarship fund for surgical students in the name of Palo Alto surgeon Dr. Blake C. Wilbur has been established at Stanford University School of Medicine.

Dr. Wilbur, general surgeon at the Palo Alto Medical Clinic for the past 42 years, is also emeritus clinical professor of surgery at Stanford.

The endowed fund was established by Mrs. Douglas T. Burch of Redwood City, a patient of Dr. Wilbur. Gifts are being added by other friends and patients.

The fund will be used to provide scholarships to surgical students, interns and residents at Stanford.

Dr. Wilbur received his A.B. degree from Stanford in 1922 and attended Stanford Medical School for two years before obtaining his M.D. from Harvard in 1925.

He was one of the eight founding partners of the Palo Alto Medical Clinic in January of 1930. Since that time, he has maintained his surgical practice at the Clinic, while continuing his active involvement in training surgical interns and residents at Stanford.

Dr. Wilbur is the son of the late Dr. Ray Lyman Wilbur, former president of Stanford University and dean of the Medical School.

He and his wife of 49 years, Mary, reside in Palo Alto. They have four children, two sons and two daughters. Their son, Dr. Richard S. Wilbur, is currently Assistant Secretary of Defense for Health and Environment.

Editors and Science Writers:

The following story concerns a new Stanford program to combat heart disease through the use of mass media campaigns. This represents the first time the media will be used in a community setting (Watsonville and Gilroy) in an attempt to persuade people to change high risk habits. It will also mark the first attempt by scientists to critically evaluate whether or not the media can play an important role in behavior change efforts. To determine the success of the campaign, a before-and-after comparison of heart disease risk factors will be made in a random sample of 500 individuals in Watsonville and Gilroy.

You are invited to send your representatives to a press conference on Thursday, September 7, at 10:30 a.m. in Room M114 at Stanford Medical School. Dr. John Farquhar, head of the interdisciplinary research team, and Dr. Henry Breitrose, associate professor of communication, will discuss the program.

Additionally, two television spots which will be utilized in the media campaign will be shown at the press conference. Prints of these television spots will be made available to all television stations attending the conference.

ADVANCE FOR P.M. RELEASE THURSDAY, SEPT. 7

STANFORD -- Stanford University researchers today (Sept. 7) announced plans to launch a new, community-based program to help prevent heart disease, using mass media campaigns in an attempt to persuade people to change high risk habits.

The project represents the first time that newspapers, television, and radio will be employed in a behavior change effort at the community level. It also marks the first attempt by scientists to evaluate critically whether or not the media can be used successfully for this purpose.

An interdisciplinary research team headed by Dr. John W. Farquhar, associate professor of medicine at Stanford's School of Medicine, will begin implementing the program next week in the community of Watsonville. Several other Northern California towns will be involved during the next few months.

Watsonville and Gilroy will receive the initial mass media, behavior change campaigns for a period of one year, Farquhar said. To determine the success of the campaigns, a random sample of 500 individuals per town will be selected for before-and-after comparison of heart disease risk factors such as blood pressure, body weight, and levels of blood sugar, fats and cholesterol.

Along with the media campaigns, virtually concurrent one-year research studies related to the causes, prevalence, and risk factors of heart disease will be conducted in Tracy and the communities San Mateo County.

Farquhar stressed that all planning for the project was done in close cooperation with local heart associations and medical societies, and civic organizations in the involved communities. "Their input was solicited from the beginning," he said, " and they've been very enthusiastic about the project. Without their cooperation and interest, we simply couldn't have gotten off the ground." -more-

The program has been in the planning stage since it was established a year ago with the support of two grants from the National Heart and Lung Institute. The grants, due to run at least five years, totalled over $750,000 the first year and are projected at nearly $4 million for five years.

In the next several years, the researchers plan to conduct further studies and behavior change campaigns in other California towns.

Farquhar said the Stanford project represents the type of preventive efforts needed to help stem the "epidemic" of heart disease in this country, which claims the lives of over 600,000 Americans per year.

"Most of the deaths of people under 65 in the United States due to coronary heart disease are preventable," he said. "We believe that success in achieving substantial behavior change at the community level lies at the root of any future national campaign to reduce premature mortality from heart disease and stroke."

Farquhar identified several high risk habits which will be targets of the media campaign, including smoking; physical inactivity or lack of exercise; gaining excess weight; and consuming increased amounts of cholesterol, saturated fats, sugar, salt and alcohol. Physicians have long associated these habits with heart disease.

"We're not advocating that people make massive changes in their lifestyle, just small but significant ones," said Dr. Henry Breitrose, associate professor of communication and a member of the research team.

"Our message will be a simple one--minor changes in a person's daily activities can significantly reduce his heart disease risk factors."

The campaign, which will be conducted in both English and Spanish, will utilize radio and television spots, press releases, recipe columns in local newspapers, a "cooking for your heart health" cookbook, and possibly other media.

A subgroup of certain high risk individuals will receive an intensive follow-up campaign, Farquhar said. These "triggering" sessions will consist of frequent meetings of the high risk group with "change agents" from the Stanford research team in an encounter group atmosphere.

Preliminary testing of the individuals in the random sample will begin next week in Watsonville and in Gilroy in mid-October. The data-gathering efforts in Tracy and in San Mateo County communities are due to begin in November.

Initially, home interviews will be conducted with individuals in the random samples to explain the nature and goals of the project, Farquhar said. Then, a survey center will be established in each town, where those in the sample will be given physical examinations and tested for prevalence of heart disease risk factors, including body weight, blood pressure, and levels of blood fats, cholesterol and sugar.

"At the end of a year, we'll come back to check the same things in these same people," Farquhar said. "In addition to behavior change, we'll be looking for beneficial changes in attitude, motivation, and information."

-more-

In obtaining this data, tests and examinations at the survey center will be supplemented by detailed written questionnaires.

The before-and-after aspect of the Stanford project distinguishes it from previous behavior change efforts, Farquhar noted.

"Money has been spent in the past on media campaigns to change behavior and get people to do the right thing," he said, "but no attempt was made to find out whether they worked."

Involved in the planning of the project and the production of the media campaign has been a research team consisting of physicians, behavioral scientists, journalists, television and film specialists, dieticians, exercise physiologists, and statisticians.

Dr. Nathan Maccoby, professor of communication, is co-principal investigator of the project with Dr. Farquhar. The media campaign is directed by Janet Alexander of the Department of Communication. Dr. Peter D. Wood, senior scientist at the Medical School and deputy director of the program, will supervise testing for levels of blood lipids (cholesterol, fats, and other compounds).

Farquahar noted that the Stanford project, initiated last June with the establishment of a Lipid Research Clinic and Specialized Center of Research (SCOR) in arteriosclerosis, reflects a new federal commitment to the prevention of heart disease. Fifteen SCOR centers and 12 Lipid Research Clinics focusing on arteriosclerosis detection and prevention have been developed nationwide since the National Heart and Lung Institute began the program last year.

A vast number of civic organizations, medical groups, and individuals in the involved communities have worked closely with the Stanford researchers in the development of the project, including: county medical societies, health departments, and comprehensive health planning agencies; local heart associations; community hospitals; chambers of commerce; mayors' offices; city councils; and local newspapers, radio and television stations.

STANFORD -- Development of a new brainwave test which reveals a person's sexual preferences was announced Friday (Sept. 1) by a team of Stanford University psychiatrists.

The test, which utilizes sophisticated computer techniques, is believed to open a new era for research by providing scientists for the first time with an objective test of a person's arousal to any outside stimulus presented in the form of a photograph (slide), the psychiatrists said.

By measuring arousal to sexual stimulation more objectively, psychiatrists will be better able to evaluate the effectiveness of psychiatric treatment in child molesters and other sex offenders.

The technique of studying brainwave responses to photographs is also expected to have broad application to areas beyond the study of deviant sexual behavior, the psychiatrists emphasized. It can be used as a tool for measuring progress in other forms of psychiatric treatment.

In fact, one of the psychiatrists on the team, Dr. Ronald M. Costell, now at the National Institute for Mental Health in Washington D.C., plans to apply this technique in studies of family interaction. He will study brainwave responses to photos of family members in families undergoing therapy as a group.

Besides Dr. Costell, the Stanford research team includes Drs. Donald T. Lunde, Bert S. Koppel, and William Wittner. Their work is reported in the August 25 issue of Science, a professional journal. The studies were conducted under the auspices of the Veterans Administration at the Palo Alto Veterans Administration Hospital, an institution affiliated with the Stanford Medical School.

The researchers subjected groups of 12 male and female volunteers to exposure of photographic slides showing male nudes, female nudes, and sexually "neutral" silhouettes (the latter a female, but sexually indistinguishable back-lighted human figure). All of the volunteers were connected to a brainwave machine (EEG) through electrodes glued to their scalps. The EEG in turn was fed through a computer for analysis of the E brainwaves.

-more-

E-brainwaves

222

E brainwaves, or expectancy waves as they are called, because they occur when a person is in a state of anticipation, would be indistinguishable visually in an ordinary EEG tracing. E waves typically occur between a warning stimulus and the main stimulus.

Results showed that when the volunteers viewed a preferred sexual image in the photographs, there was a marked increase in activity of E waves.

The most important development in the experiment took place when E brainwaves in male volunteers increased in response to the "neutral" figure as they went through 25 trials of exposure, while the female volunteers showed precisely the opposite pattern.

"This suggests," the researchers said, "that as the experiment progressed, both male and female volunteers came accurately to perceive the picture in the 'neutral' slide as a female.

"Such response pattern lends support to an interpretation of E-wave enhancement when a person views preferred objects."

The findings, according to the researchers, indicate a clear relation between the level of E-wave activity and the expected degree of sexual interest to which these volunteers were exposed.

The results also support the potential utility of the method as a research and clinical tool for determining objectively sexual interest and preference patterns in both males and females," the researchers added.

STANFORD -- The search for new understanding and improved diagnosis of Hodgkin's disease will be continued at Stanford University School of Medicine under a two-year $62,721 grant from the John A. Hartford Foundation, Inc. of New York.

The grant, the second from the Foundation to Stanford in support of Hodgkin's disease research, was announced jointly today (October 31) by the Foundation's president, Harry B. George, and Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

Hodgkin's disease is a form of cancer affecting the lymphatic system, which plays a part in the body's ability to fight infection. The disease kills some 4,000 Americans each year.

The Stanford investigators plan to utilize cell staining, tissue culture, and electron microscopy techniques to study the natural history of the disease, increase the accuracy of diagnosis and determine the response to therapy.

The project is being directed by Dr. Ronald F. Dorfman, associate professor of pathology. He will be assisted by Drs. Richard L. Kempson, Gerald Levine, Arturo Rosas-Uribe, and Irving Weissman the Department of Pathology, and senior research assistant Dede Rice.

To make a diagnosis of Hodgkin's disease, Dorfman said, pathologists must detect the presence of aberrant cells known as Reed-Sternberg cells.

The origin of the Reed-Sternberg cells is unknown. Using tissue culture and other techniques, Dorfman and his associates are investigating the possibility that these cells may be derived from lymphocytes, or white blood cells.

"We're pursuing the concept that some virus or oncogenic agent may be acting on the lymphocytes and transforming them into the Reed-Sternberg cells," he said.

Dorfman noted that the normal functions of the lymphocytes--maintaining cellular immunity and producing antibodies--can be abnormal in patients with Hodgkin's disease.

In future studies at Stanford, radioactive markers will be used to label cells from tissue removed for diagnostic purposes from patients with Hodgkin's disease. This will enable pathologists to follow the tagged cells and hopefully determine whether any transform into Reed-Sternberg cells, Dorfman said.

Additionally, continuing electron microscopy studies will focus on the relationship of Reed-Sternberg cells to others in the cell environment.

In diagnosing Hodgkin's disease, Dorfman said, pathologists must take certain cellular patterns into account. The diagnosis is complicated because other diseases, such as infectious mononucleosis, are characterized by similar cells and cellular patterns.

"We're beginning to recognize more and more the pitfalls in diagnosing Hodgkin's disease," he said. "We can recognize 'imposter' cells more clearly now, yet at the same time, there may be a relationship between these and Reed-Sternberg cells."

STANFORD -- The Annual Harold K. Faber Clinical Symposium will be held Friday (October 27) beginning at 9 a.m. in the Children's Hospital at Stanford.

Eight faculty members of the Stanford University School of Medicine department of pediatrics will present papers during the day-long meeting ranging from heart disease to new philosophies in cancer treatment for children.

Dr. Alfred M. Bongiovanni, professor and chairman of the department of pediatrics at Children's Hospital of Pennsylvania will talk about new concepts of the adreno-genital syndrome.

The Faber lecture will be given by Dr. Irving Schulman, newly appointed professor and chairman of the Department of Pediatrics in the Medical School.

A paper on "Prospectives in Nutrition" will be presented by Dr. Norman Kretchmer, the Harold K. Faber professor of pediatrics in the School of Medicine.

The annual symposium honors Dr. Faber, a distinguished San Francisco pediatrician, Stanford emeritus professor of pediatrics, and former medical director of Children's Hospital at Stanford.

The press is invited to attend. The Children's Hospital is located at 520 Willow Road.

STANFORD -- How much milk should you drink?

It's all a question of heredity, says Dr. Norman Kretchmer, a Stanford University pediatrician and biochemist who specializes in problems of human growth and development.

Professor Kretchmer's views appear in the October issue of Scientific American. He urges a review of nutrition programs for underdeveloped areas because of recent findings showing that some populations cannot digest milk.

If your ethnic background is northern European or white American, chances are that milk is okay for you. If, however, your ancestors came from non-milking regions of the world as some parts of Asia and Africa, there is a good chance that too much milk gives you indigestion.

The reason is simple. To digest milk, your body must produce the essential enzyme lactase which breaks down lactose, the milk sugar. Lactose and fats and proteins make up the three major components in milk.

In populations that drink milk the adults have more lactase and drinking milk has no adverse effects. In non-dairying populations the opposite is true. But even for most adults with intolerance to milk sugar, drinking moderate amounts of milk has seldom adverse effects and is nutritionally beneficial.

The problem of lactose intolerance, writes Kretchmer, becomes crucial with infants between the ages of two and four. Their lack of the enzyme that breaks down milk sugar is more serious and they often suffer from severe diarrhea and vomiting. The decrease of lactase after the suckling period seems to be a normal development related to evolution.

"This can have serious consequences for poorly nourished populations," said Kretchmer. "Milk is a nearly complete human food, and in powdered form it can be stored and shipped long distances. It is a popular source of protein and other nutrients in many programs, including American blacks."

The problem and its implications for nutrition are being studied by the U.S. Office of Child Development and the Protein Advisory Group of the United Nations, Kretchmer said.

"It may well be that programs of indiscriminate, large-scale distribution of milk powder to intolerant populations should be modified, or that current moves toward supplying lactose-free milk powder should be encouraged," Kretchmer suggested.

Kretchmer noted that the problem of lactose intolerance has been found to be world-wide and not uncommon. He cites both his own work and studies of more than a dozen scientists.

-more-

"That this general adult deficiency in lactase has come as a surprise to physiologists and nutritionists can perhaps be attributed to a kind of ethnic chauvinism, since the few human populations in which tolerance to lactose has been found to exceed intolerance include most northern European and white American ethnic groups," Kretchmer said.

The development of tolerance to milk sugar of some groups has been linked to heredity. One scientist, Dr. Frederick J. Simoons of the University of California at Davis, has proposed that a genetic mutation enabling man to digest lactose probably occurred at least 10,000 years ago when some groups began to milk animals.

To test the genetic hypothesis, Kretchmer and other members of the Stanford Department of Pediatrics studied members of four of the largest ethnic groups in Nigeria. These were the Yoruba in western Nigeria, the Ibo in the east, and the Fulani and Hausa in the north. These groups have different origins and occupations, and in some, milk in their diet beyond the age of weaning was introduced only in recent times.

Kretchmer took blood samples from volunteers in each group after they had drunk milk and measured its sugar content. Results showed that the Hausas and Fulanis who live in cattle-raising areas and drink milk had a lower malabsorption rate of milk sugar than the non-pastoral Yorubas and the Ibos.

Once the Stanford pediatrician had determined the distribution of lactose tolerance and intolerance in the groups, he went on to study the genetics of the problem in the results of mixed marriages.

He found that intolerance to milk sugar appears to be transmitted genetically and is probably a recessive trait -- that is, both parents must be intolerant to milk sugar to produce an intolerant child.

"The blacks brought to America were primarily Yoruba and Ibo or similar West African peoples who were originally intolerant to lactose," Kretchmer said. "American blacks have been in this country for between 10 and 15 generations, in the course of which a certain complement of white northern European genes have entered the black population.

"Presumably as a result, lactose intolerance among American blacks has been reduced to approximately 70 per cent."

The Stanford research was supported in part by grants from the Foundation for International Child Health, the Institute of Child Health in Lagos, Nigeria, the National Institutes of Health, and the National Foundation-March of Dimes. It was carried out in collaboration with the faculty of the department of pediatrics of the University of Lagos.

STANFORD -- A Stanford University hearing specialist says efforts to curb noise pollution should take into account the possible psychological effects of loud noise on man.

Up to now laws dealing with the problem have prescribed the noise volume acceptable to prevent physical damage to the human ear, said Dr. Donald A. Belt, a clinical audiologist and research associate in the Division of Otolaryngology.

"Scratching a blackboard with a piece of chalk makes little noise, but it's so irritating most people cringe," said Belt in an interview. "Listening to the roar and thunder of a symphony orchestra, on the other hand, can be simply delightful!"

Belt noted it is difficult to prove scientifically how loud noise affects man's psyche. But he added, "The absence of easily observable effects of environmental noise does not constitute scientific proof of a safe environment as some would have us believe."

A basic quality of human existence is the cyclic flow and withdrawal of energy in relation to the individual's environment, Belt said. There is activity and release of energy. Its complement is a state of rest. Health and normal functioning depend on a reasonable balance of these two states.

In vision, for example, one associates light with the activity state while darkness denotes the period of rest, Belt explained. For hearing, sounds are associated with activity while a relative quiescence is expected as a precursor for rest and revitalization. Man has no built-in defense against continuous exposure to loud noise and hence he goes partially deaf.

"We are faced with a situation in our society in which people are unable to find rest or retreat from an almost continual din," Belt commented. "In some areas, noise is heard 24 hours a day.

"Often people retreat to the remote seclusion of a mountain area, only to find themselves rudely interrupted by mini-bikes, motorcycles, snowmobiles and chainsaws.

"If we accept that quiet is important, then we must focus our attention not only on the maximum level of environmental noise which causes physiological damage, but also on the minimum which provides each citizen with the opportunity for revitalization."

One federal law, the Occupational, Safety and Health Act, requires industries to set up hearing conservation and noise abatement programs if noise levels exceed 90 decibels. New York City recently passed the toughest noise code in the nation which bans several major sources of street noise and forbids construction between dusk and dawn.

The decibel (db) is the unit for measuring sound. It is a logarithmic comparison of any given sound with the softest sound that is readily measurable. A zero-decibel sound would be close to the normal threshold of hearing. A 90 db sound would be extremely loud to the normal hearer but might be the softest one heard by a person with the maximum hearing loss; and a 135 db sound is strong enough to cause acute pain. Normal conversation registers about 55 db at the listener's ear.

-more-

Hearing Impairment

While such measures constitute a move in the right direction, Belt thinks tougher laws are needed to establish "the individual's right to quiet" at home for at least part of the day. He recommends a limit of 35 decibels or less as a permissible level for quiet periods.

Belt concedes that setting strict, quantifiable limits on offensive city sounds would be difficult to enforce with sound level meters and fines. He thinks the solution should be economic.

"When it is cheaper to own and use a quiet machine than a noisy one, we will be well on the way toward restoring tranquility in our environment," he said.

Belt recommends assessment of annual noise emission fees on motor vehicles at a rate proportional to the noise they produce. He also proposes that all commercial machines be labeled by law with their noise emission characteristics.

Belt and Dr. Earl D. Schubert, professor of hearing and speech sciences, are currently working with computers to develop an Audiological Data Bank in the Stanford University School of Medicine to study not only what constitutes normal hearing in the general population, but also to predict with reasonable accuracy the relative danger of environmental pollution.

At present the Bank has accumulated records of 30,000 persons. "Over the next five years we anticipate the accumulation of roughly a half a million records of individual hearing along with other inent data," said Belt.

The Bank covers an age range from newborn infants to geriatric patients. It relies on the cooperation of industry, public and private schools, government and local agencies, hospitals and clinics. The goal is to establish a comprehensive record of hearing and noise exposure on many individuals over a long period of time.

"The average person is almost totally unaware of his vulnerability to hearing loss," Belt emphasized. "There is neither pain nor bleeding. After noise exposure, the individual may have the feeling of temporary hearing loss, some ringing sounds in his ears, and slight decrease in ability to communicate effectively.

"After resting overnight, the symptoms may disappear, leaving the person with the impression that hearing has returned to normal.

"The fact is that hearing does not completely recover and, after many repeated insults, an accumulation of effects brings about a significant and irreversible hearing loss."

FOR RELEASE WEDNESDAY AM, OCTOBER 25, 1972

STANFORD -- Dr. Henry S. Kaplan, professor and former chairman of the Department of Radiology at Stanford University School of Medicine, last night (October 24) received the Annual National Award of the American Cancer Society for his work in Hodgkin's Disease.

Dr. Kaplan, one of the leading international authorities on cancer, was honored at the Society's annual dinner in New York City.

He was cited for "performing original clinical research, developing megavoltage radiation equipment and techniques, and combining these with imaginative application of surgery and chemotherapy for the cure and control of Hodgkin's Disease."

Chairman of Stanford's Department of Radiology for 24 years, Dr. Kaplan stepped down from his administrative responsibilities last month to devote himself more fully to teaching and research.

Earlier this year, he was elected to the National Academy of Sciences and the Academy's Institute of Medicine. In 1971, he received the Robert Roesler de Villiers Award for leukemia research from the Leukemia Society of America. In addition to awards from Italy and France, he won the Atoms for Peace Award in 1969, the only physician to be so honored.

A 1940 graduate of Rush Medical College of the University of Chicago, he served his internship and residency at Michael Reese Hospital in Chicago. He went on to the University of Minnesota and Yale before coming to Stanford in 1948.

Dr. Kaplan was one of three winners of the Society's Annual National Award this year. The others were Dr. Harold Rusch, director of the McArdle Laboratories at the University of Wisconsin and editor of Cancer Research, for his accomplishments in cancer etiology; and Sir William J. Kilpatrick of Australia, for his pioneering efforts in the development of the International Union Against Cancer.

FOR FURTHER INFORMATION CONTACT: Hali Wickner 415: 321-5310

STANFORD -- A comprehensive attack on drug addiction will be launched in a new laboratory by scientists from many specialties at Stanford University School of Medicine, it was announced today (Oct. 19).

The new addiction research laboratory will investigate the fundamental biological and pharmacological aspects of narcotics addiction and treatment. Most drug programs have focused on treatment rather than the scientific basis of addiction.

The facility will be headed by Dr. Avram Goldstein, professor of pharmacology. He has done extensive work on the basis of addiction and the effectiveness of methadone treatment. Former chairman of the pharmacology department, he relinquished his administrative responsibilities two years ago to devote his time to addiction research.

Narcotics addiction is becoming a nationwide epidemic, noted Goldstein. "With some 600,000 heroin addicts in this country, the need to prevent its spread is urgent."

Research in the biochemical and neurological mechanisms of narcotic addiction will improve the way we deal with the process in man, said Goldstein. "As we learn more about addiction, we will be able to formulate better treatment programs. We need to find out what works and what doesn't and why," he commented.

The laboratory operation will be supported in part by two grants from the Center for Studies of Narcotic and Drug Abuse of the National Institute of Mental Health (NIMH). The grants, totaling close to $500,000 a year, include an annual award of $380,200 for the next four years under a special NIMH program to fund a limited number of addiction research centers. Additional operating funds are also being sought.

The funds for constructing the building that will house the laboratory came from several private sources. The facility will be located on Campus Drive, near the Medical Center.

There, investigators of both basic laboratory and clinical aspects of narcotics addiction will work under one roof. Goldstein said he plans to continue and expand his present areas of research with the help of a larger staff. The staff will include scientists, physicians, statisticians, computer experts and administrative personnel.

Much of the work will be done in cooperation with the Santa Clara County Department of Mental Health and its methadone treatment program which Dr. Goldstein organized.

Methadone, a drug that prevents the withdrawal pains of addicts deprived of heroin, is used widely to treat and rehabilitate heroin addicts. Yet, "few well-designed clinical trials have been carried out to study dosage, duration of action, side effects or ancillary treatment needs," Goldstein said.

The Santa Clara County program is a "highly structured research program," he pointed out, which has yielded significant data on methadone treatment.

-more-

One field test underway at a Mountain View clinic involves the use of a new form of methadone which Goldstein feels may be the "methadone of the future." If is a longer acting form of methadone which is only taken three times a week instead of every day as the present form requires.

The advantage, according to Goldstein, is the convenience. Addicts will have to report to the detoxification facility less often.

This new methadone may also help stop the supply of the drug on the street. With the current form advance dosages may be distributed to addicts. Unfortunately, instead of using the methadone at home as prescribed, some addicts sell it or give it away to friends. Like any drug, however, methadone may be dangerous when not used properly, Goldstein emphasized. The new form will only be administered at the clinic.

He estimates that it will be another six months before the federal government makes any decision on the long acting methadone.

In his pharmacology laboratory, Goldstein has found that narcotic tolerance and dependence are completely reversible in mice. "If this is true for man, treatment should aim to return addicts to a narcotic-free state," he said. He favors a methadone program based on temporary support rather than maintenance, which assumes that addicts cannot function without a narcotic in their systems.

Other methadone studies scheduled to be conducted in the new laboratory include the efficiency of different dosage levels and whether the level varies for individuals, examination of side effects and observation of personality changes and rehabilitation progress during methadone treatment.

Since laboratory animals can be addicted to narcotics, animal experiments can provide new clues to narcotic addiction in man. Goldstein plans to broaden his studies on how narcotics act in the brain and what biochemical processes they affect.

His laboratory has already identified certain drug receptor sites where narcotic molecules combine in nerve cells of mice brains and guinea pig intestines. Additional studies on this narcotic binding substance, he believes, may clarify how the drug triggers biochemical and physiological responses in the body and how narcotic dependence develops.

Construction of the laboratory has been made possible by donations from foundations, corporations and private individuals. The donors include the Drug Abuse Council (set up by the Ford, Carnegie, Commonwealth and Kaiser Foundations); Dr. Alejandro Zaffaroni, president of Alza Corporation; Hoffman-La Roche Foundation; Syva Company; Max Palevsky of Los Angeles; Marie C. and Joseph C. Wilson Foundation; Brig. General James O. Boswell of Palo Alto; and an anonymous donor.

N. J. D'Ambrogio, an authority on sugar production and consumption, died Thursday (Oct. 12) at his home in Berkeley after a long illness.

In 1970, Mr. D'Ambrogio, a Stanford University alumnus, gave the University about 100 acres of land on the Monterey Peninsula to create a memorial to his daughter, Maureen, who died of cancer in Berkeley in 1967.

Proceeds from the gift will support cancer research in the Medical School and an endowed professorship known as the Maureen Lyles D'Ambrogio Professorship held by a faculty member engaged in cancer research.

The professorship is currently held by Dr. Henry S. Kaplan, an internationally known cancer researcher and professor of radiology.

Mr. D'Ambrogio was born in Rome, Italy, and immigrated to the United States as a boy. He began his elementary education in Flushing, New York, and his college education at the University of Colorado in 1915. He then transferred to Stanford University where he received an A.B. degree in 1917.

During the depression, while working in the investment field, he undertook independent research on world economic problems, becoming an authority on world sugar production and consumption.

Retired since 1951, Mr. D'Ambrogio lived at Kent Manor in Carmel until 1970 when he donated the property to Stanford.

Mr. D'Ambrogio is survived by his wife Bridie of Berkeley; two sisters, and nieces and nephews.

Services will be held at 4 p.m. Sunday (Oct. 15) at McNary and Morgan Chapel at Berkeley. Internment will be at Holy Cross Cemetery in San Francisco.

The family prefers that memorial gifts be made to the Maureen Lyles D'Ambrogio Memorial Fund, Stanford University School of Medicine.

STANFORD -- Dr. Paul Berg, professor and chairman of the Department of Biochemistry at Stanford University School of Medicine, has been awarded the V. D. Mattia Lectureship for 1972, for his work on how living cells make proteins.

The announcement was made recently by the Roche Institute of Molecular Biology in Nutley, New Jersey, which each year gives special recognition to a scientist for outstanding contributions to the biomedical sciences.

Dr. Berg was cited for "fundamental discoveries in protein synthesis," including the mechanisms by which enzymes activate the chemical units (amino acids) that form proteins, and the role of the genetic apparatus (nucleic acids) in their formation.

He will deliver a lecture entitled "Dissections and Reconstructions of a Viral Genome," November 9, 1972 at Hoffmann-LaRoche Inc., in Nutley. At that time, he will also be presented a $5,000 award and a certificate for his achievements.

After serving on the faculty of Washington University in St. Louis for four years, Dr. Berg came to Stanford as associate professor in 1959. He became professor in 1960 and was named Jack, Lulu and Sam Willson Professor of Biochemistry at Stanford in 1970.

A 1948 alumnus of Pennsylvania State University, Dr. Berg received a Ph.D. from Western Reserve University in 1952. In 1966 he was elected to the National Academy of Sciences and the American Academy of Arts and Sciences.

The lectureship was established in honor of the late Dr. V. D. Mattia, who served as president and chief executive officer of Hoffmann-LaRoche, Inc. He had been instrumental in creating the Roche Institute of Molecular Biology.

STANFORD -- Fierce competition and heavy flow of applicants challenge medical schools to define more clearly the type of student that should be admitted, according to two Stanford University physicians.

"Students are striving to enter an environment as competitive as that faced by applicants after World War II," said Drs. Bernard W. Nelson and Lawrence Crowley.

As a result the average student applied to three different schools in 1950, while his counterpart in 1971 applied to seven.

"The reasons for the increase in applicants need to be understood if medical schools are to develop equitable admission systems," said the physicians.

Nelson, associate dean for education, and Crowley, associate dean for planning at the School of Medicine, made their comments in the current issue of Stanford M.D., the magazine of the Stanford Medical Alumni Association.

In their article, "Who Will Be Doctors Tomorrow?" the Stanford physicians attribute the growth of applicants to a 30 per cent increase in the last two years of undergraduate freshmen who have declared majors in premedicine and dentistry, to women wishing to become physicians and to older applicants approaching medicine as a later second career.

"In addition, there has been a marked shift among undergraduates from physics, chemistry and engineering to the biological sciences and medicine," Nelson and Crowley wrote.

Nelson predicted 50,000 students will apply to U.S. medical schools in 1974. If they apply to eight schools, the number of applications will approach 400,000.

In 1971-72, only 12,361 students were admitted to U.S. medical schools.

About one out of every 10 students applies to Stanford, Nelson explained. Stanford Medical School should expect 5,000 applicants in 1974 competing for 86 positions in the entering class.

Nelson and Crowley commented that medicine and society stand to benefit from the increase in the number and quality of applicants. "But this development puts a tremendous strain and greater responsibility on the individuals who select future physicians," they said.

Plans, devised to facilitate student applications and to reduce the workload of admission committees, were termed inadequate by Nelson.

He said the situation calls for examination of admission practices in medical schools and studies to measure criteria for student selection against their career choices and performance as physicians.

STANFORD -- The taming of the surgeon is now almost complete.

This is the opinion of a Stanford University anesthesiologist who says Frankensteinian potential lurks in all advanced technology.

But now, thanks to the anesthesiologist, the surgeon behaves as "the gentleman that he really wanted to be all along," says Dr. John P. Bunker, professor of anesthesiology.

This was not always so, Bunker explains. The anesthesiologist--a nonsurgeon looking over the surgeon's shoulders--was first considered an operating room intruder and his presence was vigorously opposed.

Bunker's views appear in an article in the current STANFORD M.D., the magazine of the Stanford Medical Alumni Association. It is based on his new book The Anesthesiologist and the Surgeon.. It is the story of how the two have become partners in the operating room.

"Every operation is for the beginning surgeon an adventure into the unknown," Bunker writes. "So indeed, the sociology of the operating room of the past is recapitulated for every new generation of young surgeons and anesthesiologists, and the operating theater revives that classic old melodrama, the taming of the surgeon."

Bunker says that when he saw the movie M*A*S*H, a comedy about battlefield surgeons in Korea, he felt that he was seeing for the first time the operating room and the surgeons who work there authentically portrayed.

Hawkeye Pierce, the principal character, was the very personification of the ultimate surgeon. In Bunker's words, "He was the rugged individualist, unconcerned with conventional values and constraints; unwavering in dedication to his patients; utterly scornful of incompetence in others, and overcome with grief at his own failures.

"Hawkeye, the man of decisive action, is what the surgeon must be to meet the awesome responsibility he faces."

Surgery might be epitomized as the taking of great and often unknown risks to achieve great cures by dramatic means, Bunker comments. -more-

He adds: "To understand behavior in the operating room we must turn to the surgeon, since it is about him and his decisions that everyone and everything revolve. He is the Captain of the Ship."

"It was not uncommon a generation ago," Bunker writes, "for the surgeon to throw a tray of instruments on the floor, to rap his assistant's knuckles, or to reduce his nurse-anesthetist to tears by verbal abuse. Fear of the effects of this on the patient made such behavior an accepted form.

"The surgeon's authority was easily perverted to autocracy and tyranny, and self-confidence led naturally to overconfidence and arrogance. His high opinion of himself was often matched by his low opinion of other physicians.

"Self-doubts were incompatible with the decisive action required in surgery--therefore, the surgeon's need for the scapegoat."

In his book, Bunker does not overlook the surgeon's other little known role--that of the master entertainer.

"All members of the surgical team indulge in the 'joking and small talk,' which often serves to relieve anxiety," he writes. "But the surgeon sets the tone.

"Many surgeons are outrageously funny and enter into this role with enthusiasm. But few are genuine wits, and some have taken the opportunity of a captive, and presumably admiring audience, to indulge in character assassination, what some...have termed 'knifemanship.' "

Such was the operating room, and its principal actor, at its worst. Bunker adds, however, that under most circumstances the strict discipline of operative surgery was translated into an orderly and highly effective team effort. Authority was understood rather than expressed. Everyone knew his place.

In the early days, the majority of surgeons opposed the specialty of anesthesia, Bunker says. But today the struggle is over. Whatever the surgeon's misgivings initially, he now accepts the anesthesiologist's assistance gratefully and graciously, even enthusiastically. The good-risk patient rarely succumbs to the unexpected, and even the desperately sick usually survive.

"Occasionally, of course, operating room behavior reverts to earlier patterns--though I haven't seen a tray of surgical instruments thrown for a good many years," Bunker adds.

STANFORD -- James Antolchick, 29, a heart transplant patient at Stanford University Hospital, died last night at approximately 7:00.

Antolchick, of Tampa, Florida, apparently died of complications while undergoing surgery for a lung infection.

He received a transplanted heart in an operation at Stanford on September 22.

A former technical service representative of the National Cash Register Company, Antolchick had been severely ill with heart disease since May.

He is survived by his wife, Carolyn, and two children.

STANFORD -- Faced with financial problems, medical schools will find it increasingly difficult to aid students in meeting the rising costs of medical education, according to a study headed by a Stanford University medical educator.

The report calls on federal and state governments to increase their contributions to loan and scholarship programs, and on the medical establishment to explore additional methods for assisting students before the situation reaches crisis proportions.

As enrollments grow and the representation of students from low-income families increases, greater difficulties will be faced in finding adequate sources for student financial assistance, the report predicts.

In 1970 about $39 million was available in the United States in the form of loans and grants to assist medical students, the study shows. The need for student loans and scholarships will reach $78 million by 1975 if enrollments increase by 50 per cent and costs continue to escalate at the present rate of 5 per cent a year, according to the report.

"Because of the anticipated influx of low-income students, a more realistic figure for aggregate need may be $100 million by that time," the report adds.

The study was done under the auspices of the Alfred P. Sloan Foundation, and appears in a recent issue of the Journal of Medical Education. Its authors are Dr. Bernard W. Nelson, associate dean for education at the Stanford University School of Medicine; Richard A. Bird, vice-president, Analytical Planning Consultants, Inc., Honolulu; and Gilbert M. Rodgers, an independent consultant now in Washington, D.C.

The report shows that loans and scholarships provided under the Health Professions Educational Assistance Act have constituted a major source of support for medical students.

However, the report notes, reductions in federal support have necessitated greater dependence of students on medical school and federally insured private loans. In addition, support from private donors and foundations has grown at a low rate.

-more-

"It would be unrealistic," the report concludes, "to anticipate any significant acceleration of support from private sources to meet needs."

Nelson and his associates show that the Educational Opportunity Bank (EOB), one proposed method for dealing with the problem, is too costly from the perspective of the medical student and too risky from the perspective of the educational and financial institutions.

In the EOB loan plan for medical students, payments are contingent on career income. "It is this facet of the plan that many proponents of the Educational Opportunity Bank thought would appeal to students planning to enter low-paying careers in medicine," Nelson explained.

Nelson and his associates, however, made projections of incomes anticipated by future doctors, and found that it was the low earners who eventually repaid larger amounts to discharge their loans than graduates entering high paying fields of medicine.

The study also questions whether projections, based on current practice and current rates of growth in physicians' income would describe conditions 25 to 30 years from now.

The report concludes that privately funded EOB programs are not likely to do much good unless they get federal subsidy to lower the cost to the borrower.

"A balance between loans and grants must be maintained to ensure that the debt assumed by the student does not stifle his initiative. Loan burdens should not discourage students from embarking on a particular medical career," the report said.

STANFORD -- Dr. Richard S. Ross, director of the Cardiovascular Division at the Johns Hopkins University School of Medicine, will deliver the ninth annual John Kent Lewis Memorial Lecture Monday, October 9, at Stanford University School of Medicine.

His talk, "Natural History of Ischemic Heart Disease--Surgical Implications," will begin at 4:15 p.m. in Room M106 at the Medical School.

Dr. Ross, 48, is also Clayton professor of cardiovascular disease, professor of medicine, and director of the Myocardial Infarction Research Unit at Johns Hopkins.

He is noted for his work in many areas of heart research. Under his direction, the method of measuring myocardial blood flow with radioactive gas injected selectively into the coronary arteries was developed at Johns Hopkins.

The author of over 100 articles in medical journals and textbooks concerning cardiovascular physiology and disease, he is one of the editors of the 18th edition of The Principles and Practice of Medicine.

Dr. Ross has served as chairman of the cardiovascular study section in the National Heart and Lung Institute, and is currently chairman of the publication committee of the American Heart Association.

A native of Richmond, Indiana, he received his M.D. from Harvard Medical School in 1947. He completed internship and residency at Johns Hopkins Hospital, and in 1952 was a research fellow in physiology at Harvard. He joined the faculty at Johns Hopkins in 1954.

The John Kent Lewis Lectures are presented in honor of the former chief of the Stanford Medical Service at San Francisco General Hospital. Dr. Lewis was a 1922 graduate of Stanford Medical School. A noted pioneer in heart research, he died in 1961.

Editors: The following story is released jointly by Children's Hospital at Stanford and the Stanford University School of Medicine. Children's Hospital is a separate corporate entity located on Stanford land and affiliated with the Medical School.

STANFORD -- A new large-scale program designed specifically for the treatment of children with cancer has been announced jointly by the Children's Hospital at Stanford and the department of pediatrics of the Stanford University School of Medicine.

The announcement was made by Dr. M. Harry Jennison, executive and medical director of Children's Hospital, and Dr. Irving Schulman, professor and chairman of the department of pediatrics at the Medical School.

The cancer program is part of an effort by the two institutions to strengthen patient care and teaching activities, and to deal realistically with the problems of cancer and genetic diseases in children. The program will greatly expand the capabilities for treatment of children with cancer at the Stanford Medical Center.

The new program is directed by Dr. Jordan R. Wilbur, former head of the department of pediatrics at the University of Texas M.D. Anderson Hospital and Tumor Institute in Houston.

At M.D. Anderson, one of the largest cancer institutes in the United States, the 40-year-old pediatrician helped pioneer a dramatic new philosophy of cancer treatment. Its basic principle is that cancer is no longer invariably fatal among children.

"We believe that every child with cancer has a chance for long-term survival provided that his intensive treatment and supportive care is coordinated by an experienced cancer treatment group, and that the therapy utilized is not one that has previously routinely failed."

The basis for the improving survival of children with malignant diseases, Dr. Wilbur says, is the aggressive use of recently developed methods of therapy administered in a cooperative effort by cancer treatment specialists. These include powerful drugs, radiation treatment, and surgery, sometimes prescribed singly, but often in some sort of combination. New techniques of supportive therapy also are vital to the success of treatment.

As a result of these new methods of therapy, 50 per cent of children admitted at M.D. Anderson in 1969 are alive today without evidence of cancer since their initial treatment, according to Dr. Wilbur.

Overall, two-thirds of these children are still alive. Eight years ago, probably only 20 per cent would have fallen in the first category, and only one-third would still be alive, he said.

In his new position, Dr. Wilbur will direct a newly created Children's Oncology Unit whose program will have two other major elements--parents will participate actively in their child's care, and every effort will be made to minimize frequency and length of hospital confinements. -more-

If possible, one parent will live at the Hospital while the child is there. Not only can the parent help with routine care, but also he or she can learn to perform certain nursing tasks such as giving medication and recognizing changes in the child's condition, which can be very useful when the child is released from the Hospital.

When the child is home, the parents become an extension of the physician, helping collect and relay information about their child's condition that may be vital to survival.

Dr. Wilbur's arrival at Children's Hospital marks his return to the Stanford area and the Stanford Medical School. He was graduated from Stanford in 1953 and then received his medical degree from the University in 1961. In addition, he was in the department of pediatrics before moving to Houston in 1968.

He comes from a family of distinguished physicians. He is the grandson of Dr. Ray Lyman Wilbur, the first dean of Stanford's Medical School and third president of the University. Dr. Wilbur's father is Dr. Dwight Wilbur, prominent San Francisco internist and former president of the American Medical Association.

Children's Hospital was founded in 1919 as the Stanford Convalescent Home. It is now an independent, nationally-recognized diagnostic, treatment and rehabilitation center for children suffering from chronic disease and physical disability.

In 1968 the Children's Hospital and the Medical School agreed to develop joint programs for the purpose of reducing unnecessary and costly duplication of facilities and staff, assisting each other in attaining comprehensive medical care for children, and providing the best possible opportunities for education and research related to the problems of chronically ill and disabled children.

Other clinical activities now located at Children's Hospital include a new pediatric orthopedic service which opened this summer, a comprehensive care program for hemophilia, and programs in allergy, rheumatology, chronic lung diseases, and physical medicine and rehabilitation.

Stanford and Children's Hospital also are developing a common system of medical records, and plan to share radiotherapy and surgical facilities as well as highly specialized laboratory services located at the Stanford University Medical Center nearby.

STANFORD -- Training smart monkeys to tell sounds and push color buttons may ultimately hold the key to developing a surgical treatment for aphasia or loss of language abilities in stroke victims.

This unlikely-sounding procedure has been devised by a Stanford Medical School scientist to study why memory is impaired after one of the parts of the brain which specializes in language has been damaged by a stroke.

The scientist is Dr. James H. Dewson, III, who heads the Hearing and Speech Sciences Section of the Division of Otolaryngology.

His research, conducted in a laboratory at the Palo Alto Veterans Hospital, deals with a part of the brain called auditory association cortex. Its exact function is still a mystery except it is believed to be related to hearing and memory.

Hoping for clues, Dewson has turned to man's evolutionary past--the monkeys. He trained a dozen of them to recognize sequences of tones and noises and to then perform a complicated exercise that demands not only listening and looking but some form of "thinking" as well.

To obtain their food, the monkeys must first listen to a sequence of two sounds from a loudspeaker on a panel resembling a slot machine. The combinations are random and the monkeys must next decide in what order to press two lighted buttons, one red and one green, so that the color sequence matches the sound sequence just heard. They have previously been taught that one of the sounds is correctly matched by pressing red and the other by pressing green. The buttons remain lit until the monkeys either make a mistake or press them twice in a row correctly.

Now that they have learned this task, Dewson is introducing delays between the end of the sound sequence and the lighting of the color buttons. As the monkeys experience progressively greater difficulty in remembering the sound sequence, the pattern of this effect is plotted on a chart.

Having a record of their normal memory capacity, Dewson will then study what happens after a "stroke" is induced surgically one one side of the brain in these animals. This is important for several reasons.

-more-

In the human brain, each hemisphere seemingly has many of its own separate functions and handles problems with its own built-in strategy. Thus the left or major hemisphere of right-handed persons apparently deals with language and operates in logical computer-like fashion, while the right or minor hemisphere is largely mute and tends to put together bits and pieces into whole images but cannot verbalize what it sees or hears.

Dewson, however, points out that while strokes occurring on the dominant side of the human brain often cause loss of language abilities, the same effect in animals is impossible to show since they do not have these abilities. In fact, only recently has an auditory memory loss been demonstrated in animals after the auditory association cortex of just one side of the brain has been damaged. This suggests, Dewson explained, that in animals both sides of the brain may work equally in memory, and damage to one side yields only a partial loss.

He theorizes that one of the reasons the undamaged minor hemisphere in man does not carry fully half the language load may be due to interference or "noise" caused by the stroke damage in the major hemisphere. If Dewson is correct, eliminating surgically the pathway which conducts this interference would allow the minor hemisphere to more easily assume language functions in stroke patients. The operation would be similar to that performed in patients with epilepsy.

Dewson will test such an operation in an attempt to help monkeys that have had stroke damage on one side of the brain. The operation will be to sever some of the connections between the right and left hemispheres.

No memory improvement after this operation would simply confirm that in animals the two hemispheres of the brain can function independently of each other for the memory task. If, however, the monkeys' memory gets better after the operation, it would mean that cutting the connections across the brain has lessened the interference getting over from the damaged to the healthy side.

Dewson cautions that future clinical application of the procedure is purely speculative at this point.

But the idea seems to have caught the attention of the National Science Foundation which has given a $75,000 grant to Dewson to conduct the research.

"The implications of a positive finding would be dramatic and compelling," he said. "This line of research with monkeys is, without question, an untapped and valuable resource in our understanding of the brain and human language."

STANFORD -- Dr. C. Philip Larson, Jr., professor of anesthesia at the University of California, San Francisco, has been appointed professor and chairman of the Department of Anesthesia at Stanford University School of Medicine.

His appointment, effective November 1, was announced today (October 2) by Dean Clayton Rich.

Dr. Larson succeeds Dr. John P. Bunker, head of the department for 12 years, who resigned to devote himself more fully to teaching and research.

The 39-year old anesthesiologist has been on the faculty at the University of California since 1962. For the past six years, he has been vice-chairman of his department.

Dr. Larson is noted for his research on the effects of anesthesia on pulmonary ventilation, and his early work on the determination of the solubility and effects of anesthetic gases.

His current research focuses on the study of regional cerebral blood flow and the effects of anesthetic and therapeutic drugs on patients having sustained severe trauma.

A 1954 pre-medical graduate of Stanford, Dr. Larson obtained his M.D. from McGill University Faculty of Medicine in Montreal in 1958. Following internship at the Los Angeles County General Hospital, he served his residency at the University of California and received a one-year research traineeship at the University's Cardiovascular Research Institute.

A member of the major academic and professional societies, Dr. Larson is former vice-president of the American Society of Anesthesiologists. The author of 30 scientific publications, he has served as an editor of the journal, Anesthesiology, for the past seven years.

STANFORD -- Dr. Francis D. Moore, Moseley Professor of Surgery at Harvard Medical School, will deliver a talk Monday, December 4, as recipient of the third Louis and Dorothy Kovitz Visiting Professorship at Stanford University School of Medicine.

His lecture, "The National Enigma: Not Enough Doctors or too Many Specialists?" will begin at 4:00 p.m. in Room M104 at the Medical School. It is open to physicians and other health professionals in the community.

Surgeon-in-chief at Peter Bent Brigham Hospital in Boston, Dr. Moore is noted for his work in problems concerning the quality and delivery of surgical care.

He is author of numerous publications in the fields of gastrointestinal surgery and tissue transplantation and in the study of body composition and metabolic aspects of surgical care. He is also on the editorial boards of Annals of Surgery, New England Journal of Medicine and Journal of Surgical Research.

Dr. Moore, a member of several professional organizations, has headed and participated in surgery committees for the American College of Surgeons, American Surgical Association, United States Public Health Service, office of the Surgeon-General of the U.S. Army, National Research Council and National Aeronautics and Space Administration.

A native of Evanston, Illinois, he received a bachelor's degree from Harvard College in 1935 and a medical degree from Harvard Medical School in 1939.

For the next nine years Dr. Moore was associated with Massachusetts General Hospital, first as an intern and resident, then as a member of the Harvard faculty. In 1948 he was appointed to his present post.

He has also been awarded several honorary degrees from universities in England, Scotland and Ireland and is a fellow of the Royal College of Surgeons.

The professorship was established in 1969 by Dr. and Mrs. Louis Kovitz of Los Altos to bring outstanding lecturers to the Medical School. ###

STANFORD -- Heroin addicts may no longer need narcotics if they can learn how to cope with life realistically, according to a Stanford University drug abuse expert.

Robert Campos, former coordinator of the drug abuse program for Santa Clara County Mental Health Services, believes that lifestyle has a lot to do with addiction.

He has been appointed to coordinate a withdrawal program for heroin addicts based on this premise at the School of Medicine's new addiction research laboratory. The program is scheduled to begin for patients after January 1, 1973.

Methadone, a drug that prevents the withdrawal pains of addicts deprived of heroin, is used to treat addicts. However, that merely substitutes one drug for another, Campos noted.

At Stanford, he is working with Dr. Avram Goldstein, professor of pharmacology, to develop treatment and training techniques that will enable heroin addicts already in methadone therapy programs to gradually withdraw from any drug dependence. "Our aim is to rehabilitate addicts so they can function in life without any narcotic in their systems," Campos said.

Addicts take heroin not only because they are physically addicted, but because the narcotic provides an escape from daily problems. When they are on methadone and trying to kick the habit, they often return to heroin if something goes wrong because they do not know another way to cope with a stressful situation, Campos pointed out.

He theorizes that if addicts can develop lifestyle changes that will enable them to deal with the little ups and downs of life, they will no longer need heroin or methadone. This is the basis of the program.

Campos and his staff will work with a group of 40 heroin addicts in Santa Clara County methadone treatment programs who have specifically requested to come off methadone.

Four family counselors, trained by Campos, will work in teams of two with patients and their families. In addition to doing individual and group counseling, they will help patients handle routine problems in such areas as nutrition, childrearing, budgeting, the courts and the welfare system.

-more-

Campos, 37, said he has developed this type of approach through years of experience with addicts. A consultant to numerous mental health agencies and drug abuse committees, he has also trained community organizers and therapists.

Prior to his Stanford appointment, Campos was campus coordinator of training at the University of California, Santa Cruz, for eight months. He served as executive director of Quebrar, Inc. (a rehabilitation and drug prevention program in New Mexico)from November, 1970 to January, 1972, and before that he was with the Santa Clara County Mental Health Services for two and a half years.

Campos has also worked as director of social services and inservice training at the Tacoma/Pierce County Narcotic Center in Washington, as acting chief social worker of the alcohol and drug abuse screening unit of the San Francisco Department of Mental Health and as a research assistant at Langley Porter Neuropsychiatric Institute, University of California School of Medicine in San Francisco.

The addiction research laboratory, announced last month (October, 1972), will investigate the biological basis of addiction and the effectiveness of methadone treatment. It is headed by Dr. Goldstein who organized the Santa Clara County methadone programs.

Editors: Photo available upon request if not included with story.

The following story is released jointly by Children's Hospital at Stanford and the Stanford University School of Medicine. Children's Hospital is a separate corporate entity located on Stanford land and affiliated with the Medical School.

STANFORD -- A new service to provide consultation and treatment for children with a broad variety of skeletal and neuromuscular disorders has been announced jointly by the Children's Hospital at Stanford and Stanford University School of Medicine.

The program was announced by Dr. M. Harry Jennison, executive and medical director of Children's Hospital, and Dr. Robert A. Chase, professor and chairman of the Department of Surgery at the Medical School.

It represents an effort by the two institutions to upgrade care to children with diseases of the spine or joints and other crippling defects. In addition, it will eliminate the duplication of staff and facilities through cooperative programs of pediatric care, teaching and research.

The service is headed by Dr. Eugene E. Bleck, an orthopedic surgeon previously in private practice in San Mateo, where he developed the practice of pediatric orthopedics exclusively.

Bleck explained that the emphasis of orthopedic problems in children as a separate entity within orthopedic surgery is consistent with the derivation of the word orthopedic, derived from the Greek words "ortho" (to make straight) and "pais" (child).

A portion of the service provides teaching at various levels of medical education, including graduate students from the division of physical therapy, medical students, interns and residents in orthopedics, and pediatrics and practicing physicians.

Programs include a cerebral palsy assessment service, specialized orthopedic consultation clinics and rehabilitative orthopedic surgery.

Physicians and state agencies may refer cerebral palsy patients to Children's Hospital for short-term assessment. "The purpose," explained Bleck, "is to furnish physicians and agencies with a more refined and detailed objective analysis of the patient to assist them in reaching decisions on treatment and future planning. Furthermore, we want to collect objective data so we can follow a patient's progress and evaluate the effectiveness of treatment through the years."

Cerebral palsy is a disorder of movement and coordination caused by injury to the immature brain. It affects some 750,000 in this country and is the biggest orthopedic handicap in the state according to Bleck. Children with the disorder may have impaired use of their arms and legs, distorted hearing, sight or speech, as well as some mental retardation.

-more-

FILE COPY

The staff at Children's Hospital has developed measurable parameters for evaluating cerebral palsy patients in the disciplines concerned with their care and treatment. Specialists involved may include physical, occupational and speech therapists, ophthalmologists, audiologists, plastic surgeons and neurologists, as well as orthopedic surgeons.

In physical and occupational therapy for instance, special motor tests have been developed and the functional abilities will be measured.

Plans are also under way for a gait analysis laboratory to measure movement in children who have cerebral palsy. Special electromyographic equipment made possible by grants from the Hearst Foundation and the United Cerebral Palsy Association will be used.

The apparatus is a shortwave receiving system that can measure muscle patterns within a range of 100 feet by recording the electrical impulses active muscles generate. Patients are not "hooked up" to the machinery by any wires or electrodes, Bleck noted.

Specialty consultation clinics are held regularly on specific days at the Hospital. They include sessions for spinal diseases, foot problems, neuromuscular handicaps, joint diseases and hemophilia.

The service also provides orthopedic surgery and postoperative rehabilitation. Bleck performs all surgery at Stanford Hospital, but some patients return to Children's Hospital for intermediate and long-term rehabilitative treatment.

A building at the Hospital is presently being renovated to provide a new type of lodging for patients and their families. It will be a "hoptel" -- a cross between a hospital and a motel -- for patients who do not need to be admitted to the hospital, but do need some regular care, treatment or short-term evaluation, Bleck explained.

The facility will be much less expensive than a hospital room. Bleck said it will be used for patients coming for cerebral palsy assessment, by those in the Hospital's new cancer program which involves a parent living with the child, and other patients who do not require full hospitalization.

Before joining the full-time Stanford faculty, Bleck was a member of the clinical faculty . A graduate of Marquette University Medical School, he did his postgraduate training in orthopedic surgery at Duke University. This November he went to Duke University as visiting professor of orthopedic surgery for a week.

Bleck is a consultant to the physicians in the Northern California orthopedically handicapped schools, and is on the medical advisory Board of the State of California Crippled Children Services.

STANFORD — For many veterans of the Vietnamese war, the return home has been marred by the prospect of learning to live with a grotesque facial deformity caused by war wounds.

Hundreds of these veterans—as well as many others who have similar disfigurements resulting from cancer, birth defects, and automobile accidents—are being surgically rehabilitated through a unique program operated by Stanford University School of Medicine and the Palo Alto Veterans Administration Hospital.

The goal of the program, says its director, Dr. Donald R. Laub, is to improve not only the appearance of these patients, but also their self-concept and psychological approach to life.

"This is by no means strictly a cosmetic thing," says Laub, head of the division of plastic and reconstructive surgery at Stanford. "It's a very valid way of changing a person's life for the better."

Patients have been referred to Stanford and the VA Hospital from throughout the western U.S. and all over the world since the program began about five years ago. They usually require one or more of three services: silicone implants for facial or cranial defects; artificial eyes; and external anatomical restorations such as artificial ears, noses and breasts.

The program was initiated in the late 1960's in response to the great increase in the number of veterans returning from Vietnam with facial disfigurement. This increase was caused, Laub says, by the advent of high velocity rifles which increased the wounding power of hand weapons, and by the development of rapid helicopter evacuation which saved the lives of many wounded soldiers.

"Fortunately, over the past few years, the number of such injuries in Vietnam has dropped considerably," Laub says. "However, the services we provide also have good application for deformities caused by auto crashes, certain congenital defects, and surgical treatment of cancer."

For these patients, Laub says, surgical rehabilitation usually has a very beneficial effect on the psychological impairment which accompanies facial disfigurement.

"Self-image has a direct bearing on a patient's social and educational development," he says. "In countless cases, we've noticed just a fantastic improvement in a patient's entire outlook and approach to life once his appearance has been restored to normal."

The implants and artificial facial parts used in the program are created by anaplastologist Walter Spohn of Stanford's division of plastic and reconstructive surgery. Spohn, who recently launched the first anaplastology training program in the world at Stanford, was formerly head of the anatomical restorations clinic at the San Francisco VA Hospital for 25 years.

Since he was trained as an anaplastologist in Germany 30 years ago, Spohn has created thousands of artificial eyes. While at the San Francisco VA in the late 1940's, he developed the fast-curing, one-day process for making artificial eyes which is still utilized today.

To create artificial ears or noses, Spohn uses vinyl which is tinted to blend with the patient's skin. The replica is molded to the size and shape that fits in with the rest of the anatomy.

-more-

Once the organ is completed, it is attached with the same kind of glue that is used to fasten false eyelashes, he says. Patients can go for several days between regluings, and since the glue is waterproof, there are almost no restrictions on bathing or swimming.

Medical grade silicone rubber, one of the most physiologically inert substances known, is used to make the cranial and facial implants.

"The person's own tissue would be best, but silicone is a close second," Laub says. "It's nonreactive, can be preoperatively formed to the exact configuration desired, and is not affected by temperature change."

Spohn has created over 200 silicone implants for forehead, cranial and facial defects since beginning his affiliation with the program in 1968.

The technique for creating an implant begins with the making of a negative impression of the patient's face by applying dental alginate reinforced with plaster. After the hardened moulage is removed intact, a positive model of the face is made by filling the impression with artificial stone.

The defect on the stone model is corrected by filling it with wax, and the wax is then used to make a mold of the defect. Next, silicone rubber is inserted into the mold of the defect and shaped to fit.

"The silicone implant is baked at 400°C. under 10,000 pounds of pressure for 10 minutes and then placed in an air circulating oven for six hours," Spohn says. "After being carefully washed, sterilized and autoclaved, it is ready for implantation."

This technique was developed over the past 10 years by several physicians and anaplastologists working independently, including Spohn and Dr. Harvey Lash, clinical assistant professor of surgery at Stanford and surgeon at the Palo Alto Medical Clinic.

The surgical implantation is performed by Laub and Dr. Lars Vistnes, assistant professor of surgery at Stanford and head of plastic surgery at the VA.

"Surgically, the advantage of silicone implants is that you have the model ready to go, and you know it'll fit," Laub says. "Additionally, there's a good blood supply in the cranial area, so foreign materials can be better retained."

The surgical technique is tailored to the operative site and the condition of the defect, he says. For a forehead, cranial or periorbital implant, the incision is placed away from the implant, and a large skin flap is fashioned.

The dissection extends down to the underlying bone surrounding the defect, and holes are drilled in the bone. Then the implant is secured by permanent wire sutures placed through the drilled holes, and the flap is closed.

"The result," Laub says, "is that the patient's appearance is restored to normal, or near normal. Also, in many cases, the body's natural protection for the brain and eye is reconstructed."

For many patients, Spohn says, a silicone implant or artificial restoration represents a chance to rejoin society.

"There are a lot of people who need this work, but they don't know where to go," he says. "They're really under 'house arrest,' so to speak. They're afraid to go out because they look so bad.

"Recently, I made a restoration and an artificial eye for a young school teacher who lost her eye when she was five because of a tumor behind the eye. When she saw herself in the mirror, she was so happy she almost jumped up to the ceiling."

Editors: The recent operation of Shirley Temple Black at Stanford University Hospital has brought a flood of inquiries by women about breast cancer. The following story, prepared with the cooperation of Stanford University surgeons, attempts to answer many of their questions.

STANFORD -- Shirley Temple Black is a victim of a trouble, which may at some time or another, affect 1 in 18 American women.

More than 70,000 new cases of breast cancer are diagnosed annually. In 70 per cent of these, death can be avoided because proper treatment was sought early.

Dr. J. Garrott Allen, professor of surgery and author of a definitive study on the incidence of breast cancer, says: "The chief advance in the treatment of cancer of the breast has been the early recognition of the disease."

Allen attributes the progress to the educational efforts of the American Cancer Society.

Mrs. Black's left breast was removed last Friday at Stanford University Medical Center. A small, malignant tumor had been diagnosed the day before.

The former child movie star said she decided to publicize her operation in the hope that other women who discover lumps would not just "sit and be afraid. There is almost certain cure for this form of cancer if it is caught early enough."

A woman is often herself the first to discover a lump in her breast, said Dr. Allen. If she does, it is important for her to go to her doctor about it. Only after laboratory examination of a small sample of the suspect tissue, taken by a surgical procedure known as biopsy, can the doctor decide whether the lump is malignant.

Discovery of a malignant breast tumor before it has spread to other parts of the body increases a patient's chance for recovery.

For this reason, Allen suggests that women should ask their doctors to teach them how to examine the breasts. Success in treating most types of cancer rests with this step.

Because the breasts can be examined easily, it is possible to find most tumors by feeling for them. Every woman's annual checkup should include examination of the breasts by her doctor. She, herself, should be on the alert, between checkups, for any abnormal growth or other change.

Many doctors believe that every woman should examine her breasts regularly at the end of each menstrual period.

Surgery and radiation are both used for the treatment of breast cancer. In some cases, only one of these methods is preferred. In others the doctor may want to use both.

There is considerable controversy in medical circles about which procedure is safest and best, including radical surgery.

-more-

But this controversy is not expected to be settled unless there is a better understanding of tumor immunology. Dr. Roy Cohn, professor of surgery, said "greater refinements in immunological techniques are beginning to demonstrate the importance of natural defenses of the body in the control of malignant disease."

So far, however, the best cure rates in breast cancer appear to be obtained surgically.

Mrs. Black underwent a simple mastectomy, the surgical removal of the breast. It differs from radical mastectomy, which involves the removal of the breast plus the muscle tissue and lymph nodes surrounding it. A third type of surgery for breast cancer is called lumpectomy, involving the local removal of the lump, but this is useful only when the tumor is benign.

A precaution surgeons sometimes take following mastectomy is to apply radiation to the site of operation in order to destroy any cancer cells that surgery alone might not have been able to remove. This, however, will not be necessary in the case of Mrs. Black.

Radiation treatment for breast cancer is often used alone in very special cases. It is sometimes used before surgery to reduce the size of breast tumors that are to be removed.

In special cases at the time of breast surgery, or later, a patient's ovaries may be removed if the tumor tends to spread beyond the breast. These organs are the prinicipal source of female hormones a[illegible]ting the growth of breast tissue. Also synthetic hormones developed in the laboratory are often beneficial in treating breast cancer.

There are no known causes of breast cancer. Some patients often mention a blow to the breast and believe that this is related to the subsequent development of a tumor. Scientists agree that a single injury, such as a blow, has never been proved to produce breast cancer.

Experts believe that daughters and sisters of breast cancer patients run a somewhat greater risk of developing the disease than women in whose families there is no history of this malignancy. They do not yet know to what extent this is true and just what role family relationship may play.

Statistical studies also suggest that the risk of developing breast cancer is lower for married women than for single women and lower still for married women who have borne children.

The incidence of breast cancer varies widely according to geographic area and living habits. According to the National Cancer Institute cancer of the breast is far less common, for example, in Japan than in countries of the West.

Extensive research is now going on at various medical centers to evaluate mammography, the technique for detecting cancer of the breast by X rays. This method may find cancer before it grows large enough to be felt by the patient or her doctor, and may be useful for routine examination of large groups of women.

Studies are also going on, on an even newer technique called thermography, the mapping of areas of increased skin temperature. Scientists have found that most skin cancers are accompanied by increased skin temperature and hope to use this finding to detect breast cancer. Thermography makes use of an infrared camera to map and record areas of elevated skin temperature.

STANFORD--The new American Red Cross-Stanford University Blood Center, one of the first in the country to combine a blood gathering facility with the teaching and research functions of a major medical school, will be dedicated Sunday afternoon, November 12.

The public ceremony marking the opening of the center, located at 3330 Hillview Avenue in Palo Alto, will begin at 4:00 p.m. at the center. An open house for the public will be held from 3 to 5 p.m.

Featured speakers at the dedication will be Dr. Thomas A. Gonda, director of Stanford University Hospital, and John W. Gates, manager of the Western United States region for Red Cross.

The new blood center will supply Stanford Hospital with the major portion of its blood needs.

In the past decade the Hospital's blood requirements have increased tremendously, Dr. Gonda said, due to expanded surgical programs and progress in the use of blood components in therapy. Stanford's kidney transplant and cardiovascular surgery programs alone now require more blood than was needed for the entire Hospital 10 years ago.

Gonda said that the new center will also provide improved facilities for the training of future doctors and specialists, and for research into the fields of immunotherapy, coagulation and tissue typing.

"Progress in these blood-related areas could result in more effective treatment of leukemia and other cancers, as well as more successful organ transplantation," he said. "We also hope to develop new methods for the banking of tissue other than blood."

The 12,460 square foot building, which formerly housed offices of Control Data Corporation, has been in the process of renovation for the past four months.

The center is expected to draw approximately 10,000 units of blood during its first year of operation, said Harold Horoho, administrator of the center. More than half will be broken down for use as components, he added.

Donor blood can now be broken down into four component parts--red cells, cryoprecipitate, platelets, and plasma--so that one donated pint can be used to treat four different patients.

STANFORD -- After 16 months at Stanford University Hospital, the only home he has known since birth, Arnold Cortez is going home for Christmas.

Arnie, as he is affectionately called, is a wide-eyed youngster with long eyelashes and an engaging smile.

The appealing toddler has broken something of a record. He is the patient with the longest stay at Stanford's Premature Research Center (PRC) and certainly has had one of the lengthiest stays in the Hospital.

Staff members say they are going to miss Arnie. But his parents, Maria and Miguel Cortez of San Jose and six-year-old brother Mike, are thrilled to have Arnie home at last.

"Last Christmas he was so sick, and this Christmas he can be home with us," his mother said. "He's come a long way."

Arnie's story began August 1, 1971 when he was born at Alexian Brothers Hospital in San Jose. He was premature, weighing only four pounds four ounces, and had severe respiratory distress syndrome. The following day he was transferred to Stanford's PRC, where he has been ever since.

Respiratory distress syndrome, also known as hyaline membrane disease, is most frequently seen in premature infants, according to Dr. John Johnson, assistant professor of pediatrics. Infants need increased oxygen to help them breathe. For some reason, Arnie had considerable difficulty breathing without the aid of oxygen.

The time needed to wean a baby with respiratory distress from extra oxygen varies considerably from infant to infant, but it generally takes no longer than six months, said Johnson. For Arnie, it was a lot longer.

When Arnie was brought to Stanford, his condition was so serious he was put on a respirator. Johnson estimates that roughly one-fourth of the infants with respiratory distress require a respirator, which pumps oxygen to the lungs through the mouth or nose. In less severe cases, an oxygen head box is used. Arnie was weaned from the respirator, but he could not yet breathe without distress. Until last month he was still using an oxygen mask at times and sleeping in an oxygen mist tent at night.

Although Arnie's progress has been unusually slow, he has steadily improved. Now that he can breathe without extra oxygen, he will be able to go home. At 15 pounds, he is still underweight for his age, and unable to walk or talk well. As his lungs and body strengthen, physicians expect his physical and mental development to proceed normally.

At present, Arnie has some pulmonary abnormalities which are common in babies who have received mechanical respiration. It is believed that direct oxygen to the lungs causes certain changes in the tissue which are similar to changes seen in chronic lung disease. Followup studies of children who had been on respirators in the PRC indicate that such problems are reversible by the age of five, said Johnson.

-more-

Arnie/Premature Research Center

200

Each year some 50 critically ill newborns are admitted to the PRC, which is directed by Dr. Philip Sunshine, associate professor of pediatrics. The costly intensive care the infants require in the PRC is supported by a grant to Stanford from the General Clinic Research Centers of the National Institutes of Health.

Throughout most of his hospital stay, Arnie had full-time nursing round the clock. Special nurses were by him constantly to help him breathe, to administer nourishment and to watch for any sudden changes. He was monitored and treated with a variety of complex equipment. The bill for such prolonged intensive care over the 16 months was an estimated $50,000 said Sunshine.

The cost of care for Arnie did not come out of his parents' pockets, because he was in the PRC. Only a small percentage of ciritically ill infants are admitted to the center, because of their special research problems.

Yet another 700 critically ill infants are brought annually to the intensive care nurseries, where their stays range from a few days to several months. Unfortunately, there are limited resources to help families pay for their infants' care, pointed out Rose Grobstein, social worker in pediatrics.

"Arnie's case illustrates the need for some form of insurance or subsidy to cover the enormous costs of catastrophic illness," she said.

The Center, established in 1963, studies a broad range of problems in infants, from biochemical and physiological abnormalities to behavior patterns in newborns. With Arnie, physicians in the PRC were able to follow closely the natural history of hyaline membrane disease, a condition which can only be fully understood through further research.

Arnie's case is unusual because he required additional oxygen for such a long time and because he has survived with one of the most severe instances of respirator-induced chronic lung disease Stanford physicians have encountered. His progress at home will be closely monitored, and physicians hope that he will not need to return to the PRC. ###

STANFORD -- Hospitalization can be a traumatic experience for children. In the face of illness, the insecurity of a strange environment, and separation from family and friends, many children become very depressed.

But at Stanford University Hospital, thanks to a unique recreation program, young patients often find that hospitalization doesn't have to be an unhappy experience.

"We try to provide the children with enough new and positive experiences to minimize the possible damaging effects of hospitalization," says Betty Lovelace, pediatric recreation director at the hospital. "We want them to go home with enough good things to talk about so that their illness doesn't dominate their conversation."

The place for young patients at Stanford to "get away from it all" is the Marie Louise Graham Children's Center, located in the center of the hospital's pediatric unit. The center consists of a large playroom and an adjoining terrace area.

"Most children are depressed when they come to the hospital," Mrs. Lovelace says. "But here in the playroom, they don't feel like they're in a hospital anymore.

"In their rooms, the kids see and hear things associated with hospitals and sickness, and this depresses them. In here, it's so noisy that all they can hear are the sounds of children playing."

The playroom features a giant dollhouse, a pool table, and virtually every toy and game known to man.

"One of our doctors says this is the only hospital he knows of where the kids go home pool sharks and poker players," Mrs. Lovelace laughs.

Outside on the terrace, patients can take advantage of a ping pong table, basketball hoop, shuffleboard court, sandbox on legs ("at just the right height for children in a wheelchair"), and punching bag ("the kids need an outlet, a safe way of expressing their frustrations at a situation that's too much for them to cope with").

Each Wednesday, the young patients see a full-length feature movie in the playroom. For those too ill to be moved, the film is shown in their rooms. The playroom has also served as a stage for dramatic presentations, puppet shows, magicians, and science and art exhibits.

Many children learn to become skillful in certain arts and crafts during their stay in the hospital. They can try their hand at painting, playing musical instruments, or making things from leather, clay or other materials.

But the real keys to a successful recreation program are not toys and games, but friendship and understanding.

"The program has to be geared to the needs of each individual child and where he is on that particular day," says Mrs. Lovelace, who came to Stanford in 1967 after two years as recreation director at the Children's Hospital in Buffalo, New York. -more-

She consults with the doctors, nurses, and physical therapists in the pediatric unit each morning. If a child is scheduled for surgery, a blood test, or training in how to function with a handicap or prosthetic device, she makes an attempt to provide whatever support is necessary.

"I feel my role is primarily a supportive one and for this reason I don't wear a uniform," she says. "They can relate to me better."

For many children, hospitalization destroys the self-image of invulnerability and brings new restrictions into play which may be unbearable. Because of this, Mrs. Lovelace believes that hospitalization is most difficult for adolescents.

"For a teenager just getting hold of his identity, it's very difficult to cope with being taken from his normal routine and thrust into a hostile environment," she says. "He's separated from his family and peers, and has his clothes taken away for a hospital gown. He's assaulted on all sides by strangers and subjected to many bodily intrusions. And all this occurs when his physical condition is at a low ebb and he may have loss of bodily functions."

To counteract this, she believes, a good recreation therapy program can provide emotional support and intellectual and physical involvement.

"You have to give children a chance to retain some self-control, manipulate their environment, and maintain their sense of identity," she says. "It's important for most of them to realize that this is just a temporary interruption of the normal stream of life.

"For those who will have a permanent problem, we're trying to help them adjust to that. If we can enrich their lives somewhat by exposing them to new friends and experiences, then maybe they'll see that it's the quality of the life they lead that's most important."

Occasionally, special problems arise which require special solutions. Recently, one involved a teenage girl in the hospital for a kidney transplant.

"She was terribly depressed at having to spend her 14th birthday in the hospital," Mrs. Lovelace remembers, "and I had a feeling that an ordinary birthday party wouldn't help much.

"She loved rock music, so I thought of asking a local rock band called Gropus Cackus if they would mind coming to the hospital to play for her. I figured it couldn't hurt to try. Well, they not only came and played, but they brought her a dozen roses."

Another teenage girl, a frequent patient at the hospital for cancer treatment, was distressed at missing her junior prom.

"Two of our male volunteers, both real good looking guys, came and played the guitar for her," Mrs. Lovelace recalls. "We decorated her room elaborately and my husband brought a bottle of pink champagne for her. It may not have been as good as the junior prom, but she was really thrilled."

STANFORD -- Nineteen California Nobel Laureate scientists Monday (Dec. 11) asked the State Board of Education to reject a recommendation that would require religious doctrine about the origins of man to be given equal prominence alongside the theory of evolution in science textbooks.

In a letter to its nine members and State Superintendent of Public Instruction Wilson Riles, the California scientists urged the Board "to reject modifications to the science framework which require the addition of nonscientific material to our science textbooks."

The scientists' action is similar to that taken last October by the National Academy of Sciences (NAS). The NAS resolution called for limiting public school science texts "to the exposition of scientific matter."

In thousands of California homes, children are taught the Bible version of the origins of man. But in public schools, from grades fourth through sixth, they are confronted with Charles Darwin and the scientific explanation of man's evolution.

"Creation 'theory' is not based on science and does not belong in a science textbook," the Nobel Laureates said. "We urge you to support the recommendation of your own State Advisory Committee on Science Education in rejecting this unreasonable requirement for our science textbooks."

Religious fundamentalists have wanted the biblical version of the origins of life placed side-by-side with Darwin in the new science textbooks the Board will select at its Thursday meeting in Sacramento.

The scientists have wanted only evolution discussed in the science texts, on grounds that it is the sole scientific explanation for life's origin generally accepted.

To settle the controversy the State Curriculum Commission last month drew up a compromise proposal that would leave all mention of God and Genesis out.

But through suggested changes in wording, the Commission's proposal would change Darwin's theory of evolution from scientific explanation to simple speculation that man <u>might</u> have evolved--not did evolve from lower forms of life.

Dr. Arthur Kornberg, professor of biochemistry at Stanford University School of Medicine, wrote the recommendation seems innocuous, but it was clearly tailored to make room for the "creation theory" as an alternate to evolution.

"Conditional statements are appropriate," said Kornberg, "when multiple theories have been proposed and none of these can be eliminated by the existing scientific evidence.

"No alternative to the evolutionary theory of the origins of man exists today which gives an equally satisfactory explanation of the biological facts. Applying this requirement selectively to the evolutionary theory instead of, for example, atomic theory, is clearly not scientific but religious."

Kornberg stressed his remarks are not intended to foreclose further discussion on the validity of the theory of evolution.

-more-

"Many of its details are the subject of continuing conflicting controversy," he said. "Students should have the opportunity to be acquainted with the factual evidence on which scientists have based their conclusions. In the realm of scientific teaching, they should not be biased by assertions based on arguments of faith, but rather by scientific evidence."

In testimony before the State Board of Education last November, another Stanford University scientist, Dr. David Hogness, likened the arguments against evolutionary principles to those "advanced by the Flat Earth Society."

"To consider the story of creation as a scientific alternative to evolutionary theory would not only sow the confusion of intellectual dishonesty in our students, it would also create real difficulties in preparing our youth to contribute to the solution of many problems," Hogness argued.

The problems, the scientist explained, which depend for their solution on knowledge of the molecular mechanisms of heredity extend from the medical treatment of a variety of illnesses to the provision of an adequate food supply for the expanding population.

"Clearly we all wish our youth to understand these principles so that they may participate in their solutions," Hogness said. "But just as clearly we cannot be demonstrating how they lead to an understanding of certain human illnesses while, at the same time, denying their validity with respect to our origins."

Kornberg and Hogness in November told Board President Newton Stewart of Sacramento that they had educated their children in California and "take great pride in the quality of the education our state provides. We implore you not to make us the laughing stock of the entire world."

All of the Nobel Laureates who could be reached signed the letter Monday. They include: Luis W. Alvarez, Melvin Calvin, William F. Giauque, Donald A. Glaser, Willard F. Libby, Edwin M. McMillan, Glenn T. Seaborg, and Harold C. Urey, all of the University of California; Carl D. Anderson, Max Delbrück, Richard P. Feynman, and Murray Gell-Mann of the California Institute of Technology; Robert W. Holley of the Salk Institute; and Felix Bloch, Robert Hofstadter, Arthur Kornberg, Joshua Lederberg, Linus Pauling, and William Shockley of Stanford University.

STANFORD — A task force on nursing education today recommended a plan for a new Stanford University graduate program in nursing.

In a report to Dean Clayton Rich of the School of Medicine, the 12-member group wrote that nursing at Stanford must be a contributing segment of the Medical Center which is marked by strong research emphasis, high degree of specialization, and a focus on complex medical care.

"It is at the graduate level that nursing would complement the School of Medicine and the surrounding health care milieu," the report said.

Under the proposed plan, Stanford's baccalaureate program, in existence since 1917, would be phased out. It would be replaced by a two-year program offering a master of science degree in nursing. (Nursing school admissions were curtailed last fall pending the task force report.)

If adopted, the new graduate program would be expected to admit its first students in the fall of 1974.

Dean Rich said he is studying the report, and will forward it with his recommendations to Vice-President and Provost William F. Miller in the near future.

The work of the task force on nursing education was supported by a grant from the San Francisco Foundation.

Susan J. Brueckner, task force chairman and nursing project coordinator at Stanford University Hospital, said the present baccalaureate program is small and has little effect on the overall health care delivery system.

"But the impact of graduating 30 advanced clinicians prepared for expanded roles in health delivery would be substantial," she said.

The task force recommended that nurses at the graduate level should be prepared for new roles as nurse practitioners and clinical specialists, with strong research orientation.

Nurse practitioners would work interdependently with physicians, assuming some of the functions ordinarily performed by the physician. They would obtain health histories, manage treatment for the chronically ill, and participate in preventive medicine efforts.

Clinical nurse specialists would be prepared to assume supervisory roles in nursing care units, including the assessment of nursing care needs of patients, and development of innovative methods in nursing care.

The report also recommended that:

* the curriculum of the proposed nursing program be flexibly suited to individual needs of students;
* faculty be able to hold joint appointments in nursing and other schools of University departments.
* qualified nurses from Stanford Hospital or other health care agencies serve on the clinical faculty;
* tenure and promotion policies for nursing school faculty be consistent with those of other University departments;
* a major effort be made to recruit and seek funding for minority students;
* a new director be recruited to head the graduate nursing program.

Members of the task force included Linda Cronenwett, instructor, School of Nursing; Ludmila Davis, director, operating rooms and emergency room, Stanford University Hospital, Dr. Michael T.B. Dennis, director, physician's assistant program; Karilyn Duarte, instructor, School of Nursing; Dr. Count D. Gibson, Jr., chairman and professor, Department of Community and Preventive Medicine; Lorrie Newmark, nursing student; Grace E. Ringressy, director, School of Nursing; W. Richard Scott, professor and chairman, Department of Sociology; Barbara A. Shonk, Stanford Nurses Club; Paula Tognetti, nursing student; and Steven M. Zifferblat, assistant professor of education.

STANFORD -- Computer researchers at Stanford University have come up with a new type of patient medical record to help the doctor in making clinical decisions.

The new medical chart makes it possible to structure clinical data so that they can be fed into a computer.

The information in the"databank" can then be used flexibly to review a patient's status, past symptoms, prognostic indicators and treatment responses. In a matter of minutes, a study of the course and response to therapy of similar patients can be available.

Computers to extend the doctor's skill have been used for some time. But this is believed to be one of the first instances in which a doctor will be able to use a computer as a consultant on common clinical questions.

The new system was developed by Dr. James F. Fries using the facilities of Stanford's Advanced Computer for Medical Research (ACME), a biomedical resource of the National Institutes of Health.

In describing it in the Journal of the American Medical Association, Fries predicts that the computerized medical record will determine the quality of future health delivery systems.

"Computer storage of detailed clinical information has been feasible and useful in our clinic, and should have wide application," he said.

Fries is critical of present medical charts. He said they are designed more to meet legal requirements--to protect hospitals and doctors from malpractice suits--than to assist them in treating patients.

"Records are cumbersome, disorganized and redundant," he said. "If the patient's problems are enumerated at all, there is seldom a description of the treatment planned or an adequate recording of progress."

The Stanford computerized medical record utilizes a "flow sheet" format to display the patient's clinical history in chronological order. Each separate piece of information has a designated location. The chart is indexed and color coded for easy reference.

Progress notes by the doctor explaining his clinical reasoning are separated from flow sheets that contain all of the clinical data. The information on the chart is so organized as to encourage use of factual data rather than dependence on the memory of the physician.

In time studies, Dr. Fries and his associates found an average of seven minutes was needed to review each patient's rather bulky traditional chart, and five minutes more to write a clinical note containing only a few items from the patient's visit.

Using the computerized chart, the review process was cut to two minutes, and a five-minute clinical note now contained as many as 70 elements of new information.

-more-

Fries pointed out that the decrease in review time by the physicians has allowed closer scheduling of patients. In addition, the omission of important items from the chart becomes immediately apparent and often serves as a reminder to obtain particular information.

The first application of the new medical record at Stanford was for patients suffering from rheumatic diseases. ACME's staff is currently adapting Fries' computer program for other clinical areas at the Medical Center.

Meanwhile, Fries seeks professional adoption of the new medical chart. The computer committee of the American Rheumatism Association is deeply involved in this work, as adequate communication between health professionals or hospitals requires that a standard "language" be used to describe disease.

Clinical data in patient records constitute an enormous potential resource, Fries maintains. But it is largely unavailable, he said, because differing standards of terminology and format make comparison either statistically invalid or impossible.

As a result, according to Fries, physicians are restricted to "anecdotal" information from their professional experience and to studies reported in the literature.

Both resources are limited, he said, and they seldom are precisely relevant to a particular case at hand. Worst of all, especially in the teaching environment familiar to Fries, errors in memory may lead to mistakes in purportedly factual information given to students.

At Stanford today, computerized clinical data help overcome these failings, Fries pointed out. He cited a typical question: "What is the effect of aspirin on uric acid (and gout) levels?" The computer searches the file, collects the data, selects a suitable scale, and prints the answer in a graph.

"Any rheumatic disease and desired parameters in our databank may be reviewed," said Fries. "The databank is frequently consulted instead of a traditional medical-library-based review of the literature as the computer often contains more information directly applicable to our patients."

The procedure takes about 10 minutes and costs about $1 in direct computer time or about $10 per search, including secretarial time, computer entry and storage. This cost is expected to decrease when the system becomes widely used.

From four years of research on the new chart and clinical databank, Fries made these observations:

"The biggest impact of the computer in medicine today is not its computational ability, but rather the re-examination it forces on the system designer. The medical record is thus undergoing searching reappraisal.

"We began with a desire to use computers to tap the mass of clinical data generated every day. But when we arrived at a logical system, we found we had created a powerful tool for the individual clinician."

STANFORD -- Patients at Stanford University Hospital will now be offered a model, restricted-fat diet during their hospitalization, as part of a new educational program focusing on dietary factors in heart disease.

The changes in Stanford's patient menus, which went into effect today (January 29), will cut down the saturated fat and caloric content in the food served to most of the Hospital's patients. The changes will not affect food offerings to a small percentage of patients on certain special diets.

The goal of the project, says Dr. John S. Schroeder, assistant professor of cardiology at Stanford, is to expose patients to a model diet that they will hopefully follow at home after their discharge from the Hospital.

"We hope to demonstrate what an ideal diet is, and show the patients that it doesn't represent a drastic change in their eating habits," said Schroeder, who worked together with the Department of Dietetics in instituting the program, believed to be the first of its kind in the country.

"Many experts now believe that to prevent the epidemic of coronary artery disease in this country, Americans must change their dietary habits throughout their lifetimes, preferably beginning in childhood," he continued.

"Being on this diet for a few days in the Hospital is of no therapeutic value in itself, but the diet may be very valuable as an example which patients can take home."

Cardiologists have studied the relationship between eating habits and heart disease for many years. As early as 1965 the American Heart Association, noting that several studies had uncovered "an association" between blood fats and the incidence of heart disease, recommended a decreased intake of foods which contribute to elevated blood fats. Specifically cited were foods containing saturated fats and cholesterol, and foods high in calories.

These same food groups are the targets of the menu changes at Stanford. According to Carol Torio, director of dietetics at the Hospital, the following changes have been made:

-- vegetable oils are used instead of animal fats in food preparation;
-- low-fat and nonfat milk are served instead of whole milk;
-- polyunsaturated margarine is served instead of butter;
-- a polyunsaturated non-dairy creamer replaces cream;
-- food portions are controlled (the usual serving of cooked meat is three ounces);
-- certain desserts and pastries are not served to limit intake of concentrated sugars.

In addition, Mrs. Torio said, Hospital dieticians will also recommend that patients limit their intake of eggs, bacon, sausage, luncheon meats and cheeses, and substitute sherbet for ice cream.

None of the changes affect entrees, she noted. Also, if a patient or his doctor specifically requests an item not on the routine menu, such as whole milk or pie, a Hospital dietician can order it.

-more-

To determine whether the program succeeds in changing dietary habits at home, a selected group of patients will receive questionnaires three months after their discharge from the Hospital.

"It's probably unrealistic to expect people to completely follow this diet when they get home," Mrs. Torio said, "but hopefully they'll pick out one or two things to do. I think we might influence people to use low-fat or nonfat milk, or substitute margarine for butter."

Schroeder added: "A project like this might be effective because it is aimed at a receptive, captive audience. Patients are quite interested in their health at a time when they're sick enough to be in the hospital."

In a companion project, the Department of Dietetics is launching an educational program in the Hospital cafeteria. Each day menu recommendations will be posted adjacent to the menu board which lists the day's food offerings. Foods low in saturated fat, calories and cholesterol will be so labelled by the symbol of a heart.

Schroeder noted that these programs reflect a growing involvement in preventive health care on the part of certain hospitals. "Instead of just treating sick people, hospitals should also actively participate in health education and in the prevention of disease," he said. "With 32 million patients admitted to hospitals annually, the potential value is tremendous."

The new dietary programs are not the Hospital's first preventive public health measures. In July of 1969, Stanford discontinued the selling of cigarettes inside the Hospital.

STANFORD -- Dr. A. Ralph Rosenthal, assistant professor of surgery, has been appointed head of the Division of Ophthalmology at Stanford University School of Medicine.

The appointment was announced recently by Dr. Robert Chase, chairman of the Department of Surgery. Acting head of the division since October, 1972, Dr. Rosenthal succeeds Dr. Angelos Dellaporta who has returned to private practice.

Dr. Rosenthal specializes in eye disorders that result from systemic diseases and in the genetics of many disorders. He is also interested in glaucoma, a condition that results in hardening of the eye and is the second leading cause of blindness in the United States.

Prior to his appointment to the Stanford faculty last September, Dr. Rosenthal spent three years at the Walter Reed Army Institute of Research in Washington, D.C. There he was noted for his studies on the effects of copper foreign bodies in the eye, commonly seen in war injuries and industrial accidents.

The Division of Ophthalmology is expanding, says Dr. Rosenthal. It has a general eye clinic that treats some 9,000 patients a year, as well as several specialty clinics for various disorders.

A native of Pittsburgh, Pennsylvania, Dr. Rosenthal received degrees from Johns Hopkins University: an B.A. in 1960 and an M.D. in 1964. Following an internship at Boston City Hospital, he returned to Johns Hopkins for residency training in ophthalmology at the University Hospital's Wilmer Institute.

EDITORS: Following is background on the work envisioned for the Fairchild Center for the Neurosciences:

Stanford University's new program in the neurosciences will probe one of the most formidable scientific frontiers—the brain.

How does the brain think? How does it remember and create, and why is it both rational and irrational? These questions have tantalized man from the earliest times.

The term neurosciences stands for a conglomerate of related sciences. They go by many names—anatomy, physiology, biology, genetics, cell biology, pharmacology, psychology, psychiatry, neurology and neurosurgery, to name a few.

But their common root is that they attempt to understand the workings of the mind through the mechanism and structure of the brain and nervous system.

"An understanding of brain function ultimately will give rise to understanding of intellect, creative thought, memory and behavior in terms of molecular and electrochemical processes," said Dr. Clayton Rich, vice-president for medical affairs and dean of the Medical School.

In recent years, according to Rich, there has been a rush of research scientists from molecular biology and other fields into brain research.

Out of this massive attack there have been some significant payoffs. The brain and associated nervous system, probably the most complicated matter in the universe, has been mapped more carefully than before. The major circuits have been traced, thus giving the surgeon and the psychologist a closer fix on the operation of the brain and its relationship to complex behavioral processes.

The brain has been found to be more differentiated, and individual units called neurons to have more specific functions, than scientists ever thought.

Intervention into the brain electrically or chemically, scientists predict, may give rise to a new type of prosthesis for the blind and the deaf and for victims of crippling diseases like stroke and spinal cord injury.

As complex structures come under analysis, Dr. Rich said, the prospect of finding the cause of mysterious diseases like multiple sclerosis has increased. A treatment for Parkinson's disease that now benefits most suffers has been found, and has stimulated much new research toward more effective therapy for Parkinsonism and other related diseases.

Rich predicted that the marriage of the high-speed computer to microelectronics, electric stimulation of the brain, and electrophysiological recording methods will rapidly bring brain research into even more important breakthroughs.

ADVANCE FOR RELEASE IN MORNING NEWSPAPERS, JAN. 18, 1973

STANFORD –

The Fairchild Foundation, Inc., in the largest foundation gift to the Campaign for Stanford to date, has pledged $7.5 million to Stanford University for construction of the Sherman Fairchild Center for the Neurosciences at the Stanford Medical Center.

Sherman Fairchild, founder of Fairchild Camera and Instrument Corporation and Fairchild Industries, died in March 1971. Mr. Fairchild spent his life working at the forefront of technology. As a pioneer in the fields of both photography and aviation, he valued basic research as the forerunner of technological progress.

President Richard W. Lyman, in announcing the gift, said, "Stanford University and its School of Medicine welcome the challenge of establishing a solid base for further understanding of the human brain and nervous system.

"The establishment of the Sherman Fairchild Center for the Neurosciences will give force and focus to Stanford's strong interdisciplinary efforts in the neurosciences. Not only does the medical faculty include outstanding members in psychiatry and the neurosciences, but also the University is strong in disciplines necessary to further such research: engineering, computer science, biology and psychology.

"The opportunity for important advances at Stanford is exceptional. We are immeasurably grateful to the Fairchild Foundation for providing the key building from which this work can proceed."

The Center for the Neurosciences will provide space for the Departments of Anatomy and Physiology, research laboratories, classroom instruction, and administrative support. An auditorium and the initial elements of a student commons will be an important part of the complex, which will bear the name of the Foundation's donor, Sherman Fairchild.

Design of the complex will proceed immediately, with construction expected to begin in about a year. The Center should be completed within three years.

According to Dr. Clayton Rich, dean of the School of Medicine and Stanford's vice-president for medical affairs, "One of the most significant thrusts of medical research within the next two decades will take place in the neurosciences.

"We feel that Stanford University and its School of Medicine are now in a unique position to advance that research. The magnificent Fairchild grant presents an unprecedented opportunity for outstanding scientific achievement in the neurosciences."

STANFORD -- Dr. Daniel D. Federman, associate professor of medicine and associate dean for continuing education at Harvard Medical School, has been appointed professor and chairman of the Department of Medicine at Stanford University.

The appointment, which culminates a one-year search, becomes effective February 1. It was announced today (January 17) by Dr. Clayton Rich, dean of the School of Medicine and vice-president for medical affairs.

The new chairman will head the school's largest department, including 11 divisions from cardiology to respiratory medicine. The department has responsibility for the clinical medical training of medical students, house staff and postdoctoral fellows at Stanford.

Dr. Federman, 44, is a nationally-known expert in clinical endocrinology and hormonal influences on human sexual development.

His primary interest, however, is in teaching. Twice he won awards for outstanding teaching from Harvard medical students. Director of the school's program in continuing education since 1966, he developed numerous pioneering educational programs for practicing physicians.

As assistant chief of medical services and chairman of the committee on teaching and education at the Massachusetts General Hospital, the largest of Harvard's teaching hospitals, he was responsible for the training of the hospital's medical house staff.

At Stanford, Dr. Federman succeeds Dr. Eugene D. Robin, who has served as acting department chairman since Dr. Halsted R. Holman resigned in October of 1971.

Dr. Federman said that in addition to continuing the focus on scientific excellence and research at Stanford, he hopes to place increased emphasis on "superlative clinical care and teaching."

"Departments of Medicine should critically re-examine every aspect of clinical conduct," he said, "from the rudiments of history-taking and physical examinations to the refinements of using therapeutic drugs."

One of the challenges facing medical educators today, he said, is to prepare students for the new demands being placed on physicians.

"The cost-plus basis of medical care will no longer be tolerated," he said, "and we must learn how to rationalize the interaction among science, humanism, and economics. There are many new roles for physicians, and the old ones--such as general practioner--are being reformulated. Departments of Medicine should be able to prepare students, house staff and fellows for any role in medicine."

Dr. Federman's research and clinical interests have focused on the relationship between endocrinology and genetics. With his associates at Massachusetts General, he defined a new hereditary disorder of connective tissue characterized by dwarfism, joint stiffness, and eye defects. He was among the first to describe translocation of a portion of the human Y chromosome.

-more-

Federman appointed chairman, Dept of Medicine

222

His textbook, Abnormal Sexual Development: A Genetic and Endocrine Approach to Differential Diagnosis, published in 1967, has been widely acclaimed.

A native of New York City, Dr. Federman obtained his A.B. in 1949 and his M.D. in 1953 from Harvard. He completed his internship and residency in medicine at Massachusetts General.

After two years as clinical associate at the National Institute of Arthritis and Metabolic Diseases in Bethesda, Maryland, he served a year as a clinical research fellow at the University College Hospital Medical School in London, England.

Dr. Federman was appointed assistant professor of medicine at Harvard in 1966 and rose to associate professor four years later. In 1968 he also was appointed faculty counsellor to Harvard's chapter of Alpha Omega Alpha, the medical honorary society.

He is a diplomate of the American Board of Internal Medicine, a fellow of the American College of Physicians, and a member of the Endocrine Society and the American Society for Human Genetics among others.

Past president of the Boylston Medical Society, he is a member of the editorial board of the Journal of Clinical Endocrinology.

Dr. and Mrs. Federman have two children. They plan to live in Palo Alto.

FOR IMMEDIATE RELEASE

LOS ANGELES –

An endowed professorship in pharmacology has been established at Stanford University School of Medicine by the Donald E. Baxter Foundation of Los Angeles, it was announced Tuesday, Jan. 16, by Thomas V. Jones, Southern California major gifts chairman of the Campaign for Stanford.

The foundation's pledge of a gift of $600,000 for the Donald E. Baxter Professorship in Pharmacology brings additional support to a Stanford department which was ranked first in the nation in a recent survey by the American Council on Education.

The Baxter professor will be named at a later date, according to Dr. Clayton Rich, vice-president for medical affairs and dean of the School of Medicine at Stanford.

"Because our priority goal is to bolster the University's endowment, this splendid gift of a faculty chair gives further impetus to the campaign in its early stages," Jones said.

The foundation was established by Mrs. Delia B. Baxter in 1959 in honor of her late husband, Donald E. Baxter, a physician, scientist, and engineer who pioneered in the commercial preparation of sterile and pyrogen-free solutions and associated medical equipment for intravenous therapy.

The foundation provides funds for scientific and educational purposes with primary emphasis on medical research. For many years it has provided funds for medical scholarships and research at Stanford.

STANFORD -- Dr. Floyd Estess has been appointed director of the adult and child psychiatric clinics at the Stanford University School of Medicine, it was announced Wednesday (Jan. 10). He will also be a senior attending physician and clinical professor of psychiatry.

Dr. Estess, former director of psychiatric services at Dominican Santa Cruz Hospital in Santa Cruz, was named by Dr. Bert S. Kopell, acting chairman of the Department of Psychiatry.

The 51-year-old psychiatrist and psychoanalyst plans a major reorganization to increase the clinic's involvement with the community by offering, among other things, help for people suffering from depression. He also hopes to expand consultation services to public agencies which might find the department's expertise helpful.

Dr. Estess feels there is a need for a clinic on depression because "I think depression is a widespread problem and people ought to know it is a common thing and that there are professionals trained to help them."

Presently the Stanford psychiatric clinics offer the full range of psychiatric services, including such highly specialized areas as sleep disorders. But Dr. Estess also plans to develop a night clinic so that psychiatric services are more accessible and convenient to area patients. Also contemplated is the development of a new clinic specializing in sexual and marital problems.

Dr. Estess has appointed two other Stanford professors to clinic associate directorships and to head specialized units. They are Dr. Warren B. Miller who will direct the consultation program, and Dr. Irvin D. Yalom, who will direct the Group Therapy unit. A third appointee, Dr. Alan J. Rosenthal, will head the child psychiatry unit.

The Stanford psychiatric clinics are located next to the Stanford Medical Center complex, in a new building which houses services for about 16,000 patient visits yearly.

Dr. Estess succeeds Dr. C. Peter Rosenbaum, associate professor of psychiatry, who left the post to return to teaching and research.

The psychiatrist and psychoanalyst is a graduate of the University of California, and received his training in psychiatry at the Langley Porter Neuropsychiatric Institute, and his psychoanalytic training at the Southern California Institute in Beverly Hills. He is also a former faculty member of the University of California at Los Angeles and the University of Southern California.

He is currently also an associate fellow at UC, Santa Cruz, and a lecturer at UC, San Francisco.

Dr. Estess, his wife Emily, and six children live in Santa Cruz.

STANFORD — A $9.1 million expansion of Stanford University Hospital was approved Tuesday, Jan. 9, by the University Board of Trustees meeting in Los Angeles.

The construction, scheduled to begin in June, will enable the Hospital to expand vitally needed support facilities, increase emergency services, and add 25 intensive care beds for the complex surgical and medical procedures that have been developed at Stanford.

Dr. Thomas A. Gonda termed the project "a catch-up phase" which will provide physical facilities to correct present deficiencies.

"This is necessary," the hospital director said, "to meet the needs of patients in the community and the region, and the present teaching needs of the Medical School."

Gonda explained the present support facilities were originally designed to serve a 418-bed hospital. But with the remodeling of Hoover Pavilion in 1965, the actual beds have grown to 612. Hoover Pavilion is a hospital annex located near El Camino Real.

In addition, Gonda cited a 70 percent increase in outpatient visits since 1961, a 260 percent increase in the number of laboratory tests, and a 196 percent increase in diagnostic X-ray examinations.

Expansion of the support facilities includes laboratory, X-ray, nuclear medicine, surgical and postanesthesia recovery, pharmacy and central services.

The project contemplates construction of a 150,000 gross-square-feet addition to the present Core Building of the Hospital, and a subsequent remodeling of 32,000 gross square feet in the present Core. The new building will be located in the parking lot of the emergency room.

The building will include two finished floors in its first stage of development, with the availability of interim underground parking on the unfinished ground floor. The latter will be completed as funds become available.

The design will also permit an additional or third floor to be built later.

Exterior design of the building will blend with the character and esthetic quality of the existing medical center and the Stanford campus. The new structure will be of steel frame construction with design features that will reduce future costs for servicing, remodeling and addition of utilities. Construction will be scheduled so as not to disrupt the present operations of the emergency room.

Stanford's hospital expansion has received approval from the State of California Comprehensive Health Planning Agency, Gonda said.

Construction of the project will be financed by federally guaranteed low interest bank loans and Medical Center funds.

Architects for the project will be the firm of Caudill Rowlett Scott of Houston and Los Angeles. The Texas-based firm is also developing the Stanford Medical Center's master plan. —30— 1/9/73 cr

STANFORD -- Robert M. Butler, business manager of Stanford University's Department of Athletics and former budget director of W. P. Fuller and Company, has been appointed financial manager of Stanford University School of Medicine.

The appointment, effective immediately, was announced today (January 3) by Dr. Clayton Rich, dean of the Medical School and vice-president for medical affairs.

Butler, 52, will have responsibility for the administration of Medical School funds, the preparation of budgets and forecasts, and the financial aspects of long-range planning.

A 1947 graduate of Stanford, he has had 25 years of experience in fiscal management. After two years with Western Electric Company and 14 with W. P. Fuller and Company, he joined the controller's staff at Stanford in 1963. A year later, he was appointed business manager of the Department of Athletics.

In a related administrative move at the Medical School, Elwood C. Pierce, presently assistant controller, has been promoted to operations manager. He will direct staff salary payments and personnel [illegible]icies, administer fellowships, grants and contracts, and coordinate services needed to operate the Medical School.

Pierce, 44, came to Stanford in 1964 after 12 years with W. P. Fuller and Company. He served as assistant research administrator before being appointed assistant controller of the Medical School three years ago.

In the past, both the fiscal and operations management of the school have been directed by the controller and assistant controller. Now, these functions have been more clearly separated and are reflected in the titles of the two positions, said controller William B. Rowland.

Rowland, controller of the Medical School for the past 15 years, will take an early retirement this spring. He obtained his Master's degree from Stanford's School of Business in 1947 and worked on the staff of the University controller for seven years before coming to the Medical School in 1957.

STANFORD -- Dr. Leonard Hayflick, professor of medical microbiology at Stanford University School of Medicine, has been awarded the Robert W. Kleemeier Award of the Gerontological Society for his contributions to research in aging.

The presentation was made recently at the 25th annual scientific meeting of the society in San Juan, Puerto Rico by Dr. Rao Sanadi, chairman of the awards committee.

The award is given annually to an outstanding researcher in the field of gerontology.

Hayflick has discovered that normal cells in tissue culture have a finite lifespan. He found that their ability to survive outside the body decreases after a period of time as their genetic program is played out. This results in aging.

A native of Philadelphia, Hayflick received bachelor's master's and doctorate degrees in medical microbiology from the University of Pennsylvania. Before coming to Stanford in 1968, he was an associate member of the Wistar Institute of Anatomy and Biology in Philadelphia.

He is a member of various scientific societies and committees and on the editorial boards of several professional journals. In 1971 he was chairman of the California State Committee on health for the White House Aging Conference.

The Gerontological Society is a multidisciplinary professional society composed of researchers and educators who are interested in aging research and its applications.

STANFORD -- Weight control sessions for employees who want to take off extra pounds are now being offered by Stanford University Medical Center.

They are sponsored by the Employee Help Center, which was organized last year to provide certain social services for staff of the Medical Center.

Sessions feature a self-help approach to acquire eating and exercise habits that will aid in weight loss and control. Led by Alice Hine, nutritionist, and Pat Wood, therapeutic dietician, the sessions are held weekly for two to three months per group.

The two things people can do to lose weight, according to the group leaders, are "eat less and exercise more." They have drawn up a food plan that lists foods according to their nutritional and caloric value so that participants can plan their own menus wisely. They encourage members to expend more energy through exercise, even in simple ways such as using stairs instead of elevators and escalators. Discussions also include such topics as supermarket purchasing practices, ordering from restaurant menus and decreasing caloric content of recipes.

To encourage involvement, there is a small reward system. Initially, participants pay a fee. They can "earn back" their investment by gaining points for attendance, weight loss, food record keeping, and major changes in food or exercise routines.

"The first step is to help group members identify the behavior patterns that have been instrumental in keeping them overweight," Miss Hine says. "Then we give them guides for changing these patterns."

She stresses that success depends on the individual. "Modifying one's life style with respect to eating probably means changing the habits of a lifetime. A person has to be ready and willing to do this."

The enthusiasm and sharing of the group can provide the support one needs to effect the desired changes. The return-on-investment reward serves as an additional form of motivation, not as a police measure, Miss Hine emphasizes. "Participants learn to evaluate the effectiveness of their own diet routines," she says.

"The changing involves unlearning old patterns and relearning new ones," explains Mrs. Wood. "In behaviorist terms, it is a rearranging of the environment." For weight problems, she says it could mean keeping fewer fattening foods around the house or buying them in smaller quantities or going to a movie instead of eating out for the evening.

Participants find their own form of arrangements, Mrs. Wood continues. "The important feature [illegible]hat they are controlling their environments. When the group ends, they can continue these controls to maintain a desirable weight."

STANFORD -- Peter F. Carpenter, deputy executive director for the Price Commission in Washington, D.C., has been named assistant vice president for medical affairs at the Stanford University Medical Center.

The appointment of the 32-year-old executive in this newly created position was announced Thursday (Feb. 22) by Dr. Clayton Rich, vice-president for medical affairs and dean of the Medical School.

Carpenter will carry on a wide range of administrative duties at the Center, Dr. Rich said. His appointment becomes effective immediately.

A career civil servant, Carpenter had previously served as director of the management team for President Nixon's federal assistance review program at the Office of Management and Budget.

A native of Berkeley, Carpenter received a Harvard National Scholarship and was graduated from Harvard in 1962. His college summers were spent as a smoke-jumper for the U.S. Forest Service, parachuting into remote areas of the Pacific Coast to fight forest fires.

After graduation from Harvard, Carpenter was commissioned as a regular officer in the U.S. Air Force, and held several assignments, ranging from research into nuclear radiation effects to liaison duties in Southeast Asia. He also served in the Office of the Secretary of Defense and on the White House staff.

Carpenter earned a master's degree in business administration from the University of Chicago in 1965, and became a doctoral student in the field of organizational behavior at Stanford's Graduate School of Business. From 1968 through 1970, he was assistant director of the Center for Materials Research at Stanford.

Prior to joining the President's federal assistance review program, Carpenter served briefly as vice president of E. G. Fubini Consultants, Ltd., and as a consultant to the Secretaries of Defense and Health, Education and Welfare, as well as to the Science Advisor to the President.

Carpenter is married to the former Karen Nordlie of Denver, Colorado.

STANFORD -- A new research program to evaluate the medical team approach in the treatment of couples with sexual problems has been established at the Stanford University School of Medicine.

Funded by a $175,000 grant for three years from the Commonwealth Fund of New York, a professional team will attempt to deal with the multiple components of a patient's illness.

"Few clinical fields better illustrate the challenge and complexity of a medical problem than the area of sexual dysfunction," said the project director Dr. P. Herbert Leiderman, professor of psychiatry.

Here, anatomical, hormonal, individual psychological, and interactive social and cultural factors combine to create diagnostic and therapeutic problems of great difficulty, Dr. Leiderman explained.

The team will include psychiatrists, an obstetrician and gynecologist, a urologist, a clinical psychologist, a sociologist, social workers and nurses.

Dr. Leiderman and his associate, Dr. Ben Z. Taber, a Stanford specialist in obstetrics and gynecology, designed the research with several objectives in mind:

--to study the therapist as a participant in handling problems of psychosexual nature;

--to establish a team approach for the diagnosis and management of complex, many-faceted medical problems;

--to initiate a pilot program for the training of auxiliary personnel in the management of sexual and reproductive dysfunction.

At present, a common approach to treating patients with sex problems is through referral from one specialist to another. A patient may go to a psychiatrist who refers him to a gynecologist who may refer him to a urologist, when he suspects an organic cause of the problem.

"Rather than fragmented serial management by superspecialists seeing patients individually, the care of those patients presenting complex problems could be centralized in a therapeutic team," Leiderman said.

He added the concept of an improved team approach could be readily adapted to other medical problems.

"Sexual problems are not the only problems originating from multiple factors," Leiderman commented. "Obesity, problems involving mother-child interaction, and medical disorders with psychosomatic components such as rheumatoid arthritis and bronchial asthma could benefit from a team approach."

STANFORD — Follow-up studies of 400 patients who underwent coronary bypass surgery at Stanford University Hospital indicate that the operation has produced excellent results with improved long-term survival, a team of Stanford cardiologists and surgeons reported Saturday, Feb. 17.

"The procedure provides generally excellent results with low surgical mortality and. . .long-term survival is improved by the operation," the researchers told a meeting of the American College of Cardiology in San Francisco.

Authors of the report included cardioligists David S. Cannom and Donald C. Harrison, and surgeons D. Craig Miller, Thomas Fogarty, Pat O. Daily and Norman E. Shumway.

Coronary bypass surgery is one of the methods of treating coronary artery disease, in which the arteries leading to the heart are obstructed by the buildup of fatty materials.

In the operation, a portion of a vein from the patient's leg is used to construct a bypass or detour around the obstructed part of one or more of the coronary arteries. This enables the artery or arteries, which had previously been blocked, to deliver blood and oxygen to the patient's heart.

The operation has remained controversial since its development five years ago because of high surgical mortality and inconclusive results at some hospitals.

At Stanford, the first 400 consecutive patients to receive the operation were included in the study. The group included 335 men and 65 women with a mean age of 52.5 years. Of the 400, 256 had experienced at least one prior heart attack.

The overall operative mortality was 25 deaths or 6.2 percent of the patient population. However, the authors noted, of 249 elective patients without high risk complications such as congestive heart failure, shock, or nonfunctioning valves, there were only two deaths for a mortality rate of 0.8 percent.

Follow-up data on the 375 surviving patients revealed that 63 percent had returned to work without any angina pectoris (severe chest pain), and an additional 16 percent were free of angina but not working.

"Thus, angina was totally abated in 79 percent of those surviving surgery," the authors said.

In nine percent of the patients, there was a decrease in angina during physical exertion. Unsuccessful results included nine percent of the patients who noted no improvement or experienced a heart attack, and four percent who experienced late cardiovascular death.

The authors also reported that the outcome of coronary bypass surgery for any given patient can be predicted by consideration of three preoperative variables—degrees of congestive heart failure, electrocardiographic changes, and mitral valve incompetence.

"Good, although not absolute, predictability of outcome can be achieved if these three variables alone are considered," they said. Adding other variables did not increase the accuracy of this "index of operative success," they noted.

STANFORD -- Stanford University has appointed an association of two firms as construction managers for the forthcoming $9.1 million expansion of the University Hospital, James Nelson, director of facilities and properties, announced today (February 15).

The two firms are Rothschild and Raffin, Inc., prominent hospital contractors based in San Francisco, and McKee-Berger-Mansueto, Inc., international consultants in construction management.

Their responsibilities in managing the project will include direction of the multiple contractors who will carry out the construction, and consultation on the design of the new facilities.

The construction, scheduled to begin in June, will enable the Hospital to add 25 intensive care beds, increase emergency services, and expand vitally needed support facilities. The latter includes laboratory, X-ray, nuclear medicine, surgical and postanesthesia recovery, pharmacy and central services.

A 150,000 gross-square-feet addition will be constructed in what is now the emergency room entrance and Medical Center receiving area. Construction will be scheduled so as not to disrupt the present operations of the emergency room.

The appointment of the construction managers follows an evaluation of nine firms submitting proposals for the project, said John Lerry, Stanford's manager of construction and engineering.

In order to complete the expansion as quickly and inexpensively as possible, the University will utilize fast-tracking, in which portions of the job are under construction while the balance is still in design, Lerry said. This technique is used most effectively in conjunction with the construction management system, he added.

Architects for the project are Caudill Rowlett Scott (CRS) of Houston and Los Angeles.

STANFORD -- A $300,000 gift in the form of an irrevocable trust has been made by a California physician to Stanford University to establish a teaching and research fund in pulmonary disease.

The gift was made by Dr. Francis S. North, a specialist in diseases of the chest at the Palo Alto Medical Clinic and member of the voluntary faculty at Stanford Medical School. The trust names Stanford as the beneficiary after Dr. North's death.

The money will ultimately be used to establish the Francis S. North Medical Research and Teaching Fund, the income of which will support teaching and research activities in diseases of the chest in the Department of Medicine, said Dean Clayton Rich.

He added, "The establishment of this generous trust represents Dr. North's expression of confidence in the Medical School."

The same trust established by Dr. North also names the University of California Medical Center in San Francisco as the beneficiary of another $300,000. It will be used for teaching and research at the Cardiovascular Research Institute, according to Dr. North's attorney, John R. Griffiths, of Palo Alto.

Dr. North is a graduate of the Columbia University College of Physicians and Surgeons. He was a resident in internal medicine under Dr. James J. Waring, a noted clinician and professor of medicine at the University of Colorado. He received his training in pulmonary disease under Dr. Waring and at the National Jewish Hospital in Denver.

He has been associated with the Palo Alto Clinic since 1949 and served for nine years at the Stanford University Health Service.

Dr. North has also established the James J. Waring visiting professorship at Stanford honoring his former teacher. It is awarded annually to a distinguished physician in the field of chest diseases. In addition, he has also supported a number of fellowships at the Medical School. He is a trustee of the Francis S. North Foundation in Chicago, established by Dr. North in memory of his father.

STANFORD -- Plans for development of a research building to house the Lymphoma Virology Program of the Department of Radiology of the Stanford University School of Medicine were approved Tuesday (Feb. 13) by the University Board of Trustees.

The building, which will contain 10,000 gross square feet, will be located on eight acres of land west of Governor's Lane near the Medical Center. The structure will be of modular design, adaptable to laboratory or small classroom needs, said Dean Clayton Rich.

Estimated cost of the project is $733,000 to be mainly funded by the National Cancer Institute. Completion of the building is expected in March, 1974.

In addition, Dr. Rich said, plans for the eight-acre site will be developed for possible future laboratory needs of the University and the Medical School.

The new research program will be directed by Dr. Henry S. Kaplan, professor of radiology and cancer research pioneer. His work will deal with several aspects of the biology of human malignant cancers, including Hodgkin's disease. In the new laboratory, methods will be devised for the study of human cancer cells, with emphasis on the possible role of viruses in the cause of malignant disease.

In other action, the University Board of Trustees approved the academic program for the Sherman Fairchild Center for Neurosciences. This program will be made possible by a $7.5 million gift from the Fairchild Foundation announced last month. The buildings, located at the south corner of the medical center, will house the departments of anatomy and physiology, and will provide an auditorium for the Medical School.

The Fairchild Center will serve as an intellectual focus of efforts concerned with the central nervous system and will involve departments both inside and outside the Medical School, Dean Rich said.

FOR IMMEDIATE RELEASE

STANFORD –

Providing health care for all Americans now requires a universally available funding system.

Whether developed exclusively by the government or through a combination of private and public means, this insurance program must include effective cost controls and strong incentives for changing the present system of delivering health services.

Otherwise it will simply stimulate higher costs like those which have followed the introduction of Medicaid and Medicare.

Provision of health care services should remain primarily within the private sector with greater public accountability. Wherever possible individuals should have a right to choose among varied systems of health care.

Until an effective system of national health insurance with cost controls becomes operative, wage and price controls will be a needed element in governmental actions about health services.

These conclusions are reached in a new book on *Medical Care and Medical Cure,* edited by Spyros Andreopoulos, information officer at the Stanford Medical Center.

Published by the Sun Valley Forum on National Health and the Millbank Memorial Fund (251 pp., paper, $3), it reflects the views of 33 experts participating in last summer's forum and includes six invited papers on this topic.

Participants for the most part were professors and health care specialists. But they also came from related professions, such as sociology, economics, labor, and insurance.

While recommending top priority for a program of national health insurance, they emphasized the need to preserve pluralism in providing services mainly through the private sector and to achieve far-reaching changes within the entire health care delivery system.

"If social policy is to concern itself with financing health services alone, and if doctors continue to go along with the public demand for curing the incurable, they could bankrupt the nation and succeed only in supplying a constantly deteriorating quality of service," Andreopoulos said.

The medical care industry now involves between $80 and $85 billion annually, accounting for about 7.6 percent of the gross national product (GNP).

Projections by the Social Security Administration indicate costs are climbing at 10 to 15 percent annually, a trend which would require 9.8 percent of the GNP by 1980.

"The resources devoted to health services cannot be unlimited," the symposium participants agreed. "These resources must therefore be organized and administered effectively."

Present health care is characterized by a high level of scientific knowledge and technological skill and health professionals with a strong commitment to high-caliber, individual service.

But the system within which physicians and others now operate to provide care is "inefficient, inequitable, and often ineffective," the participants said. "The quality of care rendered varies widely and costs are rising rapidly."

As government involvement in the payment of medical care has progressively deepened, demands for public acountability have increased under a growing, vocal, consumer movement.

"Because physicians dominate the marketplace for medical care. . .generally free of the normal constraints imposed by consumer demand, the sum of their individual decisions, as to type of specialty and site of practice, very largely determines the allocation of all health resources," the symposium agreed.

"This largely unconstrained process has resulted in serious maldistribution and misallocation of resources. Sources of primary or family care have been shrinking even as the demand for personal health care services has been rising.

"In medical schools there has been a heavy emphasis on medical specialization and biomedical research and little attention to health services research—or how American families can be assisted to find points of entry and guidance through the health delivery system."

(more)

Financial barriers at the point of entry to this system should be greatly reduced, the seminar emphasized. "What is needed is a universal, comprehensive system of financing to support good medical care for everybody," without a means tests or a history of prior financial contributions.

Universal coverage of a minimum of specified services "is compatible with pluralism in the delivery of services. To the extent possible, people have a right to choose among systems of care and should be left options to choose among health care providers."

Families should be encouraged to have "a continuing relationship with a stable source of medical care," the symposium indicated.

"Prepaid group practice plans or health maintenance organizations. . .offer consumers an opportunity to participate in policy and program development and to benefit from related services that are continuous, professionally sound, and cost contained. They merit high priority support and financial encouragement."

In an introductory chapter, Andreopoulos said the experts believe "the present health care arrangements can be structurally and humanely improved, not through a national health service, but within the context of a continued pluralistic system.

"The provision of services should remain in the private sector except in special situations where government efforts are needed. . . . The pluralistic approach may not satisfy some who believe in neat organization charts, but the right of free choice for doctors and patients is, according to these experts, worth preserving in a free market system."

In one of the invited papers, Dr. Paul Ellwood Jr., whose studies led to the health maintenance strategy for the Nixon administration, warned that the "likelihood of change in the health system is relatively low," even though Congress probably will act favorably on "virtually everything we have sought with respect to Health Maintenance Organizations (HMO's) except adequate health insurance coverage for everyone."

"The health industry is a highly regulated one, whose regulatory controls are dominated by practitioners and their professional societies and associations, and focused on the activities of individual practitioners," Ellwood noted.

Comprehensive health planning organizations "tend to be dominated by the providers" of care, he explained and "some have tried to use their authority to thwart HMO's from acquiring needed [hospital] beds.

Congress has created a "Health Services Corps" to alleviate the shortage of physicians in underserved areas, but carefully structured this to give medical societies jurisdiction over the program. Other agencies proposed to control hospital bed use also would vest control in physicians.

"The ultimate direction of these and other actions is toward an almost totally regulated but structurally unchanged health system [in which] the possibility of innovation and change would be virtually nil," Ellwood warned.

One hopeful factor, he added, is that "virtual consensus" has developed on the need 1) to encourage the formation of larger health care organizations able to integrate the components of health care delivery and 2) to provide every consumer the purchasing power necessary to obtain basic health services."

The report urges that "serious consideration" be given to the direct public assumption of responsibility for certain services such as emergency care.

"Most physicians in practice have abdicated on this score," according to Dr. Avedis Donabedian of the University of Michigan. "Consequently, this standby function has gone by default rather than design to the hospitals, which are not quite sure what to do with it."

Harvard Prof. Rashi Fein, well known health economist, argued that unless payments from a national insurance system are channeled through a single payment mechanism, it will be difficult to achieve important changes in the health care system.

The largest savings in expenditures are likely to come as ways are found to affect utilization of these services rather than price. Since use is basically determined by the physician rather than the patient, "efforts to contain the total costs. . .required that the programs be structured to provide incentives to change physician behavior," Fein declared.

Legislation limited to the financing of the purchase of health services could make present problems "more severe," he warned, providing "a good deal less health or equity than we should with the resources available."

Dr. Kerr L. White, Johns Hopkins professor who recently headed the President's Science Advisory Committee panel on health services research and development, observed that "improved incentives for more adequate financing will involve greater public accountability—and this means effective regulation of use, costs, and quality" of health care.

(more)

Dr. Cecil G. Sheps, vice chancellor for health sciences at the University of North Carolina, noted that the "very success and rewarding character of medical service" to the individual physican explains why there is "virtually nothing in [his] training and background, and too little in his experience, to prepare him to give advice which is relevant to the need of the community as a whole" rather than individual patients.

"A physician can work hard all day doing his best for patients who have access to him—and do them a lot of good," he added. "At the end of the day, he naturally believes that he has spent his day in the most effective way.

"This may not be, and often is not, the case. Too often the patients who do not have acess to him, and the health problems he does not tackle, are of much greater importance to the community."

Sheps maintained that a controlling role for the consumer is "essential for the future sucess of a pluralistic health system."

Fein noted that physicians "would to well to consider that if there were a truly competitive market in medical care, there would be significant, impersonal economic controls on their decisions.

"It is not surprising that physicians prefer the U.S. pattern under which they can control the market forces. What is surprising is that the layman has come to accept that situation as an essential freedom" for physicians, he added.

The elimination of the fee-for-service payment, which can be achieved through prepaid group practice, "would go a long way toward eliminating the incentive to overdoctor," he said. The physician's income then would not depend on the sheer volume of services rendered.

In a similar vein Yale Prof. I.S. Falk stated, "The system must have an end to the near-total dominance of the provider of medical care. . . .

"The needed remedies for the system are fundamental and massive, not to be satisfied by applying bandaids, prescribing aspirin, or relying on the healing effects of time, nature, and nonintervention."

While financing and fiscal management should be "monolithic," as in social security, Falk added, the "availability and provision of services should be private and pluralistic.

"Alternative patterns of organization . . . should not only be permitted but even encouraged," especially for making comprehensive care available on a prepaid basis.

A national "health security" program could cover about two-thirds of the current expenditures for personal health services, later extending to 80 or 90 percent coverage as manpower and other resources are developed for dental and other services.

The initial phase would cost about $63 billion by 1974-75, he estimated. Total expenditures without such a program might reach $93 billion.

Financing would come mainly by rerouting present expenditures, including private insurance, individual payments from noninsured individuals, and from public funding of such categorical programs as Medicaid and Medicare, Falk said.

The dread of dying from some dramatic diseases has produced a demand for cures and a serious imbalance in medical research and education efforts, Andreopoulos reported. "The biologic needs of our population are insatiable, especially if physicians place their emphasis on curative medicine."

For example, Jean Hamburger, a leading French nephrologist, recently estimated that if all Frenchmen who would benefit from it were supplied with kidney dialysis, the cost would consume over 80 percent of France's total social security budget.

Copies of the book may be purchased direct from the Milibank Memorial Fund, 40 Wall Street (59th floor), New York, NY 10005.

FOR IMMEDIATE RELEASE

STANFORD — A report from a panel of experts to the National Academy of Sciences released Sunday, Feb. 11, predicts that 8,000 new cases of cancer could be caused annually if high-flying supersonic planes should damage the earth's thin layer of ozone in the upper atmosphere.

The 46-page report by a group of scientists chaired by Dr. Kendric C. Smith, a Stanford University biochemist, based its estimate from the progressively higher incidence of skin cancers near the equator where persons receive greater exposure to sunlight and ultraviolet radiation.

The scientists said there was not enough information to draw positive conclusions about the effects of the once proposed 2,000-mile-per-hour supersonic transport (SST), but they commented: "Sufficient knowledge is at hand to warrant utmost concern over the possible detrimental effects on our environment by the operation of large numbers of supersonic aircraft."

Congress scrapped the American SST program in 1971 on grounds of noise and atmospheric pollution, but debate on the SST effects on the atmosphere was quite limited, Dr. Smith said.

Life on earth is partially shielded from biologically harmful solar ultraviolate radiation by a thin layer of ozone in the upper atmosphere. Scientists disagree on whether operation of fleets of SST's would alter the ozone of the stratosphere, thus increasing the amount of solar ultraviolet radiation reaching the earth.

But the panel said if these activities should lessen the amount of ozone in the stratosphere, there would be a high probability of significant harm to humans and to other life systems.

Because of the radiation-absorbing properties of ozone, a small decrease in ozone concentration would result in a large increase in ultraviolet radiation reaching the earth's surface in the wavelength range 280-320 nanometers (billionths of a meter). A five percent decrease in ozone concentration, for example, would yield a 26 percent increase in the intensity of the most biologically damaging ultraviolet radiation.

The scientists recommended gathering information on the wavelength distribution and intensities of ultraviolet radiation at several locations on the earth's surface to provide a baseline from which to evaluate possible future environmental changes. This information would also provide needed knowledge relating to incidence of skin cancer to the amount of ultraviolet radiation received.

Biochemical repair mechanisms exist in most living organisms, the panel said. One molecule easily altered by sunlight is deoxyribonucleic acid (DNA) which carries an organism's genetic blueprint. Increased amounts of ultraviolet radiation may overload natural repair mechanisms with serious effects on biological systems.

Certain marine life, plankton for example, also may be threatened by increased levels of solar radiation, the scientists indicated. It recommended that accurate measurements of the depth of penetration of ultraviolet radiation in natural waters and studies of the reaction of marine life to ultraviolet light intensities be done.

Members of the panel included Paul Bener, Observatorium Davos, Switzerland; Martyn M. Caldwell, Utah State University; Farrington Daniels Jr., Cornell University Medical Center; Arthur C. Giese, Stanford University; Timothy H. Goldsmith, Yale University; William H. Klein, Smithsonian Radiation Biology Laboratory; John A.H. Lee, University of Washington, Seattle; and Frederick Urbach, Temple University Health Sciences Center.

STANFORD — To see again through clear eyes the sights obscured for years seems like a miracle for many. Thanks to eye banks, some 1,500 Americans each year can experience that miracle.

The Stanford University Hospital Eye Bank is one of the West's largest suppliers of human eyes for transplants. Its work is made possible in part by the volunteer efforts of the Cambrian Park Lions Club.

For almost a year now, the club has delivered eyes from Stanford to wherever they are needed for surgery and research. Since the service was started last March, club members have driven a total of 5,600 miles to transport more than 125 eyes, according to Paul Graton, head of the project.

The part of the eye used for transplants is the cornea. It is the "window" of the eye—the clear membrane in front which lets in the light, explained Dr. Mathea Allansmith, assistant professor of surgery and head of the eye bank.

Donor eyes must be removed within six hours after death and used for transplants within 24 hours. Immediate transportation is crucial. Teams of Lions Club members are on call round the clock to transport eyes as they become available.

The Hospital notifies the eye bank after a donor has died. (The candidate or a relative has already given permission for the eyes to be used after death.) If Stanford does not have a candidate for corneal transplant, the eye bank will contact another physician who can use the eyes.

When notified, the Lions team on call picks up the eyes and rushes them in a special container to their destination. Most of the deliveries are local, but mercy missions have taken members as far as Stockton. Graton himself has traveled over 2,000 miles for the eye bank.

The Cambrian Park Lions are the only volunteer group in the Bay Area who deliver eyes, said Graton, although Lions chapters throughout the country do work in sight conservation.

Dr. Allansmith said that the club's services are a tremendous help to the Stanford Eye Bank, which runs on a minimal budget. "Some 300 corneal transplants are done yearly in this area," she noted, "and because of the Lions, eye bank personnel do not have to interrupt their work to make deliveries."

A specialist in immunology and diseases of the external eye, Dr. Allansmith explained that the corneal transplant is the most successful type of tissue transplant, with only a 25 percent failure rate.

She said that a large number of transplants are done for a deformity of the cornea that causes it to bulge and become cone shaped. The condition, called keratoconus, is common in young people in their twenties and generally affects both eyes. Other indications for transplants include corneal ulcers or scars, and in older patients, swelling due to water in the cornea which prevents the cornea from remaining clear.

Unlike kidneys or hearts, corneas do not have to be typed and cross matched for transplantation. At Stanford, however, donor eyes are typed, but not intentionally matched to the recipient. Researchers are conducting follow-up studies to determine if there is a relationship between cross matching and failure. Results so far have indicated that tissue incompatibility is not a significant factor in corneal transplant failure, according to Dr. Allansmith.

"The health of the cornea and the skill of the surgeon are most likely the key elements for a successful transplant," she said. "Furthermore, improved surgical techniques and instruments are probably more important for lowering the failure rate than cross matching."

Corneas can come from donors of all ages, even if they wore glasses, had cataracts, cancer or a number of other systemic disorders. "As long as the cornea itself is clear and undamaged, it can be used," said Dr. Allansmith. As a general precaution, however, she said that no corneas are used from persons who had viral infections of the liver.

STANFORD — "No more training grants?" "Will we survive?"

Deans, faculty and young investigators at the Stanford University School of Medicine this week seemed to be repeating these questions to themselves, to Washington officials and their Congressmen as news of federal budget cuts for health were spelled out in the President's budget message.

For the Stanford Medical School, the proposed phasing out of federal training grants would mean the loss of $3,378,000 per year.

The federal action may put the School in the unenviable position of being unable to fulfill its commitments to some of the 271 trainees in its pre- and posdoctoral training programs, according to Dean Clayton Rich.

In anticipation of official word from Washington, Dean Rich took steps to freeze all new departmental appointments until further notice.

He also began a review of the effects of the cuts on other School operations. Training money supports the departments in which students are learning and a significant portion of it goes for faculty and staff salaries.

Presently, the National Institutes of Health (NIH) supports training efforts at the School for three to five years. It is on the basis of this commitment that Stanford has hired faculty and accepted trainees. According to Washington reports, however, all training programs would be phased out in three years.

Rich termed the cutbacks "a reduction between muscle and bone," not "fat and muscle." He said they will reduce the School's training capacity because there is no way adequate private funding can be obtained in a short time.

The federal training programs were put into effect 20 years ago to help medical schools attract young scientists. They have supported predoctoral and postdoctoral students in fields such as anatomy, physiology, biochemistry, genetics and microbiology.

In addition, the training programs have enabled medical doctors to seek specialization and to do research in areas covering the whole range of clinical disciplines.

Stanford departments expected to be hardest hit by cuts include psychiatry, medicine, radiology, biochemistry, genetics, microbiology, pediatrics and pharmacology.

Nobel prize winning geneticist Joshua Lederberg said termination of grant support for training "will have catastrophic consequences."

"It is especially obtuse," he said, "to terminate these training programs when women are at a point of finding their just parity, and when many minority group students have found their way through undergraduate programs to qualify for leadership in the sciences."

(more)

2/2/73 cr

Lederberg said the only rationale the Administration can give for these cuts is that we have a surplus of trained manpower. "This is hardly true in the biomedical sciences."

Paul Berg, professor and chairman of the Department of Biochemistry, said the federal action signals "the virtual dismantling of the foremost health sciences research program in the world."

Berg's department which has 25 postdoctoral fellows, in addition to medical students, is doing research in the causes of cancer at the basic biochemical level, and in the mysteries of the genetic code.

"People have to realize," Berg said, "that it isn't that the trainees look over the shoulder of the professors—they are the ones doing the work. If there is no money to support them, the research—or at least a substantial part of it—isn't going to be done."

Malcolm Bagshaw, professor and chairman of the Department of Radiology, said there may be justification for cutting back certain programs. "But there are fields in which we don't have enough trained physicians and researchers."

Bagshaw said, "We only have one-third of the radiation therapists we need to give proper therapy to people with cancer in the U.S."

In the light of the President's war on cancer, it would be a disaster to cut off the supply of people who can do therapy and research, he said. "The budget cuts will probably force us to trim some research programs and eliminate others entirely."

In another area of proposed cutbacks, close to $1 million is involved in Stanford's Regional Medical Programs (RMP) for area III. This includes 11 counties in mid-California from San Mateo, Santa Clara, to San Benito, Monterey and San Joaquin.

According to Dr. William C. Fowkes Jr., Stanford RMP coordinator, these programs have helped extend resources of Stanford Medical School to outlying communities, including the development of programs for better patient care.

A wide variety of projects has come out of the Stanford RMP, including a new organization for dental care for Indians, medical services for migrant workers, a plan for rehabilitating stroke patients, development of coronary or specialized care units in local hospitals, and establishment of community clinics.

Specific programs, promised funding for three years, but now threatened, include emergency care for critically ill newborn infants, using helicopter service to transport them to Stanford Hospital, a new community health center in Daly City which plans to train aides in home care, and training of community health workers at West Valley Community College.

Another program being affected is the training of physicians' assistants. It was launched at Stanford in 1972 with RMP helping to finance the initial phase. Aim is to improve the distribution of health professionals and delivery of primary care in poorly served inner-city and rural areas. Forty students are enrolled in the program. The two-year curriculum is run jointly with Foothill College.

Federal withdrawal of support of RMP "would restrict our activities, enrollment for the next class may be cut down, and we would have staff cutback of 20 percent," predicted Dr. Michael Dennis, program director.

Associate Dean Count Gibson, who serves on a review committee for new projects seeking RMP aid, said the program is "not a slush fund, no give-away, I've never seen a wiser use of money."

Gibson termed the demise of RMP as "arbitrary and mindless."

He said it would be more appropriate to look at what the federal withdrawal will mean for the country, not for Stanford University alone.

STANFORD -- A Stanford University surgeon says politicians are overinflating the public's expectation of doctors.

They make promises as they introduce health care legislation that cannot be met with dollars alone, says Dr. Robert Chase, professor and chairman of the Department of Surgery at the Stanford University School of Medicine.

"The concept of total freedom from disease as a right, and the physician's total responsibility for it, is a dangerous social illusion," he concludes.

Chase's remarks appear in an article on "The Physician Image: Expectation versus Reality" in the current issue of Stanford M.D., the magazine of the Stanford Medical Alumni Association.

"It is clear," Chase writes, "that public expectations go well beyond what physicians can do for individual patients.... The new doctor is expected to cope with overpopulation, famine, slums, pollution, traffic, racism, political corruption" and more.

Politicians, says Chase, must share some of the blame for the public expecting too much from doctors. "The politician characteristically looks for a scapegoat, and where health care is involved, there is no one more vulnerable than the American physician. There is, in a sense, a tendency to cast the M.D. in the villain role."

Chase cited these examples: when Sen. Edward Kennedy's health subcommittee hearings were held in 1971 to "hear the people on the health crisis," the proceedings, "had all the earmarks of a political campaign," says Chase. "In my view they lacked objectivity and played upon emotionalism."

In another instance, John Knowles, a prominent figure in medicine, was quoted as saying, "M.D.'s are the largest single purchasers of Lincoln Continentals." The Massachusetts Medical Society invited Knowles to document his allegations, but his response was, "I'm not going to diddle around with those jerks." The medical society, says Chase, censured him.

Chase says the news media has also been responsible for developing the physician's public image, with "repeated derogatory articles and presentations."

The now defunct Life magazine last year published an editorial "Our Sick Medical System," then was surprised to see the results of a poll of its readers: 68 percent thought their treatment was good to excellent; 70 percent thought their doctors cared about them personally; only 15 percent considered their care poor.

The Stanford surgeon notes that surveys and analyses have shown the typical patient is very complimentary about his own doctor, but uncomplimentary about "most doctors and organized medicine."

-more-

He cites the Louis Harris poll in 1972 showing that college students rate the M.D. as "dedicated man," though they feel his fees are too high. Another survey indicated that respondents expressed more confidence in medical leadership than in any other field.

In another study ranking occupations, the physician was number two in prestige behind only the Supreme Court justices. Congressmen rated 8th, lawyers 11th, ministers 17th, and newspaper columnists 46th.

Stating that "physicians do care deeply about their public image," Chase suggests measures that might be taken to improve it.

"On a personal level," he recommends "it is important to reverse the vicious circle of mutual alienation which currently exists between the patient and physician, in which the patient suggests that physicians are 'machines' and 'money grabbers' while at the same time physicians call the patients 'ingrates.' "

He says physicians must readjust the image of organized medicine by participating in it more, and participating less in activity that appears to have self-interest rather than interest in the public. They should also avoid Madison Avenue tactics to paint a new image. "It has proven ineffective and actually counter productive."

"Organized medicine," he says, "must show evidence that it is willing to discipline itself through active peer review, and more active disciplinary actions against physicians who abuse their privileges."

Chase notes that in 19th century America, the family doctor became a trusted and respected community member, often idealized and glorified. With the rise of scientific medicine censure of medical skill became less frequent.

"The physician's image today is hardly a glorified one," says Chase. "We cannot return to the day of the country practitioner. One cannot quarrel with the technical direction of contemporary medicine. Its success is too apparent."

Advances in medicine are both a glory and a curse, he says. They make possible miraculous cures, but they also make medical care more complex, expensive and less personal.

But he adds: "As physicians we do recognize that public patient confidence is an important part of total medical care."

###

Mailed March 27, 1973

In 19th century America, the family doctor was glorified, with novelists depicting him as a composite of all the qualities of human perfection.

There is a tendency to cast the M.D. in the villain role, as a "money grabber."

A prominent physician was censured by the medical society for his unsubstantiated comment, "M.D.'s are the largest single purchasers of Lincoln Continentals."

STANFORD — Stanford University faculty and staff members will be evaluated on their risk of developing heart disease in a one year medical survey beginning next week on the campus.

The screening project is part of the Stanford Heart Disease Prevention Program, a five-year, Medical School based effort funded by the National Heart and Lung Institute.

All Stanford employees 26 years of age and older are eligible for the survey, said physiologist William Haskell, coordinator of the project. Participation will be on a voluntary basis.

"The purpose of the program is to determine the frequency of certain characteristics associated with a high risk of developing premature heart and vascular disease," Haskell said.

"For the participants, this is an opportunity to learn more about their own 'heart health' status and contribute to research on how to prevent heart attacks."

The survey, which has been approved by the University administration, will begin April 2 and continue through March of 1974. It will be conducted at several sites on the Stanford campus, near various employee groups, and at the program's offices at 730 Welch Road.

Approximately 5,900 Stanford employees are eligible, and some 4,500-5,000 are expected to participate.

"It is important that we have a high response rate," Haskell said. "The higher the percentage participating, the more representative the information will be of the entire Stanford population. If only a small sample responds, it could mean that only people with known medical problems are participating."

For most employees, the screening will consist of a 15-minute health evaluation, including a brief medical questionnaire, measurements of height, weight, and blood pressure, plus cholesterol and triglyceride (fat) analysis of a blood sample.

Approximately 25 percent of the participants will be asked to return for a second, more extensive evaluation. This group will include a random sample, as well as individuals who were found to have high blood fats in their first visit.

The second evaluation will include a more detailed questionnaire, more extensive blood tests, a urine sample for protein analysis, resting and exercise electrocardiograms, and a brief cardiovascular examination by a physician.

Results of both the initial and second evaluation will be made available to the participants or their physicians on requests.

This week eligible Stanford employees will receive a letter asking them to participate in the survey.

The Stanford Lipid Research Clinic, part of the Heart Disease Prevention Program, will conduct the survey. Nationally, 12 Lipid Clinics are participating in a collaborative effort to determine prevalence of heart disease risk factors. Dr. John W. Farquhar, associate professor of medicine, is the director of the Stanford clinic.

Heart disease is the leading cause of death in this country and kills over 600,000 Americans per year.

Science Writers: Embargo date on this story is dictated by the scientific publication of this paper in the Lancet.

(ADVANCE) FOR PM RELEASE MONDAY, MARCH 26, 1973

STANFORD -- A Stanford University scientist and a British medical research team Monday (March 26) reported they had successfully tested in human volunteers an effective preventive remedy against the common cold, which could have usefulness in the future.

The remedy, called interferon, is a protein purified from human white blood cells infected by viruses. The substance is secreted by the cells to interfere with--or prevent--the viral infection of other cells.

The scientists stressed interferon is still too costly to produce and far from being a practical remedy. But, "it is likely," they said, "that given a definite clinical application, techniques will be improved, the cost of interferon will decrease and the method of administration will be simplified."

Findings showed that interferon could also delay the start of influenza B infection, leading the scientists to believe that the agent could prevent influenza if the proper dose could be given.

"This is the first agent known to prevent common cold infections in man," the researchers noted. They said that "interferon given to the volunteers in the study had no adverse effects."

The research was reported in the current issue of Lancet, a medical journal. The scientists are Dr. Thomas C. Merigan, professor of medicine and chief of the division of infectious diseases at the Stanford University School of Medicine; and Drs. Sylvia E. Reed, Thomas S. Hall, and David A. J. Tyrrell of the M.R.C. Common Cold Unit at Harvard Hospital, Salisbury, Wiltshire, England.

The investigation was supported by the British Medical Research Council. Merigan's work was done in England during his sabbatical leave. The latter was supported by the National Institute of Allergy and Infectious Diseases of the National Institutes of Health and by a fellowship from the Guggenheim Foundation.

In an interview, Merigan said the studies were made possible because human interferon production and purification techniques have improved in recent years.

"Interferon holds promise as a broad-spectrum antiviral agent for respiratory disease," he predicted. "Given to people early before a predicted epidemic or individual infection, it could protect them against several different types of viruses."

But it will require development of new technology before interferon could be mass produced for general public use, Merigan said. An effective dose of the agent produced with present methods costs several thousand dollars. Merigan expects methods for making the antiviral protein in greater quantities to be developed now that its effectiveness in man has been demonstrated. "I hope the findings will act as a stimulus."

-more-

The Stanford scientist and his British associates obtained interferon for their experiments from Finland, aided by one American and a group of British pharmaceutical companies. Finland and the Soviet Union are currently producing interferon in greater quantities than the United States.

In the experiments conducted in England, Merigan and his colleagues gave interferon by nasal spray to 16 volunteers prior to exposing them to a common cold virus. The volunteers were known to be susceptible to the specific virus.

By increasing the daily dosage of interferon to 14 million units and by employing four days of treatment, the scientists were able to prevent the symptoms completely. Thirteen out of 16 volunteers who received a placebo developed common cold infections after exposure to the virus. (A unit is the minimum amount of interferon that inhibits a standard virus in tissue culture.)

Their earlier studies with 22 volunteers, half of whom acted as controls, showed that interferon doses as large as 1 million units were ineffective in preventing influenza, but there was some delay in the appearance of symptoms in the treated patients.

Merigan explained that the lower dose of interferon given and the large amount of influenza virus required to infect the susceptible volunteers may explain why the agent did not work.

When influenza occurs naturally, the amount of virus is probably small and this may account for good anti-influenzal effects with small amounts of interferon, he said.

Russian scientists have reported effective results against influenza virus with smaller interferon doses, Merigan said, but efforts to duplicate the Soviet experiments in England had been unsuccessful.

Merigan said the British studies may be viewed as a beginning in defining the minimum effective dose of interferon needed to prevent respiratory disease. However, further study will be required to define what might be the most practical regimen.

Since its discovery in 1957 in England by Alick Isaacs and Jean Lindenmann, interferon has been looked at as a potentially useful weapon against viruses. But the idea of making interferon outside the body to use inside the body was regarded as impractical. Scientists, including Merigan, turned their attention to developing drugs that stimulate interferon production in the body against viruses. Unfortunately, these drugs proved relatively ineffective and difficult to use in man.

Efforts have also been in progress at the National Institutes of Health to define the molecular structure of interferon. If the effort succeeds, it could be a major scientific breakthrough, eventually allowing scientists to synthesize interferon in the laboratory.

Meanwhile, interferon production depends on the supply of white blood cells obtained from blood donors. Interferon is made when white blood cells are exposed to a virus and incubated in tissue culture fluid. The cells secrete interferon which is collected, purified and tested for unwanted contaminants before it can be used in man.

Production costs are high and, according to Merigan, obtaining interferon this way is presently impractical. The United States has no centralized blood banking system, and it would be difficult to standardize production and to establish proper quality controls.

At the moment, the most promising source of interferon seems to be cells grown outside the body. "In the last two years, significant progress has been made in producing human interferon in acceptable tissue culture cells other than white blood cells, and there is every expectation that greater yields can be produced in the future," Merigan said.

STANFORD -- The first class of physician's assistants being trained at Stanford University Medical School has begun working with practicing physicians in communities throughout California for the final phase of instruction.

Starting today (March 26) the 16 physician's assistant students will spend the last 12 weeks of their two-year program assisting a community doctor in various primary care tasks.

Under supervision of their medical preceptors, the trainees will perform a broad range of services, from taking medical histories and doing physicals, to suturing minor wounds and removing casts.

These paramedics are being trained to help improve health care delivery in underserved rural or urban areas. They will enable physicians to direct their skills and energies to the most pressing medical problems.

When the newly-trained physician assistants graduate in June, they will be qualified to take both state and national certifying examinations which will be given next December.

"The physician's assistant may be the first person a patient encounters in the doctor's office, but he or she cannot make a diagnosis or prescribe treatment without consulting the primary care physician," explained Dr. David Clark, associate director.

The Stanford program, sponsored in cooperation with Foothill Junior College, leads to an Associate of Science degree. It is one of two programs set up in California since the state authorized physician's assistants in 1970. The other program is run by the University of California in Los Angeles and the Charles Drew Medical Center in Watts.

Applicants to the program must have a high school diploma or the equivalent. According to Dr. Michael Dennis, director, members of disadvantaged minority groups and people from areas with inadequate medical services, are particularly encouraged to enter the program. Stanford will try to place its graduates where health care personnel are needed.

The class now going out to the communities consists of nine former Army medics, six registered nurses and one Bachelor's degree recipient. Their preceptors were selected from among physicians who had expressed interest in the physician assistant concept when Stanford conducted a state-wide survey before setting up the program.

During their first year, students take courses at Foothill until June to fulfill requirements of the A.S. degree. Their science courses include anatomy, physiology, biology, psychology and philosophy of primary care. The next four months are spent in classes at Stanford where they learn about common medical problems.

After more than a year of classroom preparation, the trainees participate in clinical rotations through services at the Medical Center and affiliated health care facilities to gain firsthand experience in dealing with patients. They then devote their final 12 weeks to practicing what they have learned with a doctor in a community.

-more-

The physician's assistant program at Stanford is supported by grants from the Bureau of Health Manpower of the Department of Health, Education and Welfare, and the California Regional Medical Program.

In addition to the class nearing the end of its program, another class of 20 is in its first year. Applications are now being accepted for a third class scheduled to begin this fall.

The 16 trainees and the communities they have been assigned are listed below.

STANFORD -- A new clinical program for the diagnosis and treatment of patients with neuromuscular diseases has been established by the Department of Neurology at Stanford University Medical Center.

The program provides the combined services of two new facilities--an outpatient clinic and a diagnostic laboratory--said Dr. David A. Prince, department chairman.

Clinic patients include those suffering from various forms of neuromuscular disease, such as muscular dystrophy and myasthenia gravis.

These disorders are characterized by prominent muscle weakness and fatigue, diminished muscle size, muscle pain or cramps, and difficulty in walking, Prince said.

The neuromuscular clinic was organized by Dr. Judith Koehler, assistant professor of neurology and a specialist in neuromuscular diseases and child neurology. It provides a full diagnostic evaluation, including specialized examinations and laboratory tests, she said.

In the diagnostic laboratory, small biopsies (samples) of muscle tissue from patients are stained and examined microscopically. This procedure, together with a clinical evaluation, provides an accurate diagnosis, Prince said.

Treatment for many patients with neuromuscular diseases involves medications as needed and a program of physical and occupational therapy.

The clinic and laboratory will operate as a referral center, Prince said. Prospective patients should be referred to Stanford by their private physician.

STANFORD -- Living human cells, stored and grown in a Stanford University medical research laboratory, will be orbited in outer space for 28 days to determine the effects of prolonged weightlessness on their ability to survive.

Cultures of the human cells will be put aboard Skylab, the U.S.' first manned orbital space station scheduled to be launched from Cape Kennedy May 14.

Stored in tiny chambers in a specially designed instrument package, the cells will be fed automatically with nutrients during the mission. The cells' movements in tissue culture will be recorded by time-lapse photography.

During their normal duties, Skylab's astronauts will check from time to time if the hardware is working. While in-flight data are being obtained, an experiment package on the ground will be operated at the same temperature as the in-flight package. This information will be available to permit comparison of the cell growth in earth gravity.

At the end of 28 days, the cells will be retrieved in the Pacific Ocean by an aircraft carrier, and flown to San Diego and then to Stanford where scientists will study the effects of zero gravity on their growth.

"This marks the first time that scientists will be able to assess the effects of prolonged space flights at the cellular level," said Dr. Leonard Hayflick, professor of medical microbiology at Stanford and co-investigator on the NASA project.

"We have no information regarding either subtle or perhaps even major effects that might take place at the cellular level," the Stanford microbiologist explained.

"It is probably not too far-fetched to assume that there are effects on the human cell's ability to divide normally at zero gravity that are not expressed in the short time that astronauts have lived in space.

"The more subtle effects following brief exposures must be determined if dangerous consequences are to be anticipated and avoided during future space explorations."

FILE COPY

-more-

Hayflick said he plans to study the basic genetics of human cells exposed to weightlessness. Among these will be possible chromosome breakage, the same kind that is frequently produced by drugs.

The NASA project was designed and is directed by Drs. Philip Montgomery and Joseph Paul of the University of Texas, Southwestern Medical School in Dallas.

The human embryonic diploid cells that will be used in the experiment have been preserved in the super cold of liquid nitrogen for 11 years. They are called diploid cells because they have the correct shape and proper number of chromosomes known to be normal for man--that is, 46. Because these cells are known to be normal and free of contaminating viruses, they are being used all over the world as a growth medium for manufacture of human virus vaccines and for cancer research.

The cells are also used for Hayflick's studies in aging. He found these cells will double 50 times and then die because all embryonic human cells are "programmed" that way. When the cells are thawed for use, they "remember" the number of doublings they had achieved before being frozen.

The cells that will be used for the NASA experiment are at the 10th doubling level, Hayflick said.

Skylab will be launched atop a giant Saturn 5 booster and sent into a 269-mile-high orbit of earth.

Next day, a smaller Saturn 1-B rocket will loft an Apollo command ship with three astronauts on board on a similar orbital path to rendezvous and dock with Skylab. The astronauts will remain there for the next 28 days.

According to NASA, Skylab's mission will have far-reaching consequences. It will help determine if man can live and work in space for extended periods of time necessary to make round trips to other planets or moons.

STANFORD -- Roads around Stanford University Medical Center are being changed as part of the Hospital's $9.1 million expansion scheduled to begin in July.

Part of Quarry Road is being replaced and a new link to Campus Drive is being built. Work on these routes has already begun and will be completed by July 15, according to the Health Facilities Planning Office of the Medical Center.

The new addition will allow the Hospital to increase vitally needed support facilities, emergency services and intensive care beds. It will be an extension of the north side of the Hospital Core Building, and is expected to be finished in January of 1975.

During the construction, the existing emergency room entrance will be maintained. When the addition is completed, there will be new emergency and service entrances to the Hospital.

By June, the two service roads south and east of the Medical Center will be closed to through traffic. The Palo Alto bus will make its usual stop in front of the Medical Center, and then swing around to Campus Drive.

###

STANFORD--For the first ten years of his life, Martin Fierro was an outcast, the victim of a facial deformity which made his appearance grotesque and left him barely able to speak.

Today, following a delicate operation at Stanford University Medical Center to correct his double cleft lip and palate, the cheerful youngster from Mexico is talking enthusiastically and looking forward to attending school for the first time in several years.

"He never would have been able to get a job or go to school," said Dr. Donald R. Laub, who performed the surgery on Martin at Stanford. "Now he can become a productive member of society."

Martin was born with two gaping holes in his lip beneath each nostril and a large opening in his palate. His nose was snubbed down to where his upper lip should have been.

He was one of seven children raised by his father in the remote mountainous village of Mocorito in Sinoloa, Mexico. After being harassed unmercifully by neighbors and classmates for several years, he became a virtual recluse.

"Martin had such a grotesque defect that the other kids constantly would laugh and throw rocks at him," said Laub, head of the division of plastic and reconstructive surgery at Stanford. "So he was finally forced to drop out of the first grade three or four years ago."

A few months ago, the boy was discovered at a clinic in Mocorito by Dr. Dale E. Hoyt, president of an organization called the Flying Samaritans. Founded by a group of doctor-pilots, the Samaritans run several medical clinics in Mexico and provide free air transportation when needed by patients and physicians.

The Samaritans flew Martin to Stanford on March 14. Five days later, the operation was performed. Professional fees were waived and hospitalization costs were covered by Project Concern, a non-profit agency which assists in providing health care to the poor.

Facial tissue from the boy's cheeks was used to construct an upper lip. The nose was pulled out, and the narrow piece of skin between the tip of the nose and the lip was formed. The large opening in the palate was closed, and the palate was pushed back in good position for speech.

The result of the surgery, said Laub, was "instant rehabilitation."

"The change in Martin's outlook has been just as dramatic as the change in his appearance," the surgeon continued. "When he first came to us, he was very shy and withdrawn. Now, he's unbelievably happy."

Because of his advanced age, Martin was strong enough to have his lip, palate, and nose repaired in a single operation, Laub said. In younger children, correction of a similar deformity would require three operations.

-more-

Surgery to correct a cleft lip and palate is rarely performed on a child of Martin's age in this country, Laub said. Such problems usually are handled through Crippled Children's Services, enabling most American children to have the necessary surgery before they are two years old.

Some 150 patients, nearly all of them children, have been brought to Stanford from Mexico, Latin America and Hong Kong for surgical rehabilitation in the Medical Center's INTERPLAST program (INTERnational PLASTic and reconstructive surgery).

Most of the children require reconstructive surgery for a cleft lip and palate, severe burns, or syndactyly (webbed fingers), Laub said. Recently, a few have undergone orthopedic or cardiac surgery.

Surgical services are donated by a team of Stanford surgeons headed by Laub. Free air transportation is provided by Pacific Southwest Airlines (PSA) or the Flying Samaritans. Drugs are donated by several pharmaceutical companies.

The average cost of hospitalization and operating room use is roughly $425. These expenses usually are covered by Project Concern or private donations.

During their rehabilitation, the children stay with foster parents in the Bay Area. Approximately 150 sets of parents serve in this capacity for the Stanford program, Laub said.

Martin's foster parents are Mr. and Mrs. Raphael Arbizo of San Jose. Though his speech will never be perfect, the boy is communicating very well now, Mrs. Arbizo said. He presently speaks only Spanish, but is trying to learn English.

For the Stanford surgical team, as well as the other groups involved, the project is a very rewarding one.

"We'd like to do one of these cases a week," Laub said. "Through this surgery a miraculous change is made in a person's life."

STANFORD -- Doctor William R. Fair, associate professor of surgery at Stanford University School of Medicine, is recipient of a Research Career Development award from the National Institute of Allergy and Infectious Diseases of the National Institutes of Health (NIH).

The purpose of the award is to foster the development of young scientists with outstanding research potential for careers of independent research in the health sciences, according to the NIH.

A specialist in urinary tract infections, Fair is the first urologist in the history of the NIH to be granted such an award, noted Dr. Thomas Stamey, head of the Medical School's division of urology. Most such awards have gone to internists and basic scientists, he said.

Fair will receive $25,000 annually for the next five years to support his studies on the biochemistry of the prostate gland and its secretions. This research may provide clues for the diagnosis and treatment of urinary tract infections, infertility and prostatic cancer, Fair said. He will spend most of the award period at Stanford, but also plans to work at the Institute of Reproductive Biochemistry and Physiology at Cambridge University in England during the 1974-75 academic year.

In 1956, working with Stamey, Fair discovered that prostatic and seminal fluids contain a potent antibiotic substance that kills bacteria responsible for urinary tract infections. He plans to investigate the biochemistry of this antibacterial factor and its importance as a defense mechanism against infection in humans.

Fertility may also be related to the secretions of the prostate and accessory glands. Indications are that sperm are more motile in certain supporting plasmas, according to Fair, and he will pursue studies he and his colleagues have begun in this area.

He is also working on the development of a radioisotope scan that can be used for X-ray diagnosis of prostate cancer. Currently, the only way to diagnose cancer of the prostate is by feeling the gland during rectal examination. "A radiologic scan would provide a more objective means of diagnosis," said Fair.

Examination of the prostatic fluid may also provide a way of diagnosing prostatic cancer in the future, said Fair, but much more detailed biochemical studies are needed.

A native of Pennsylvania, Fair received his B.S. from the Philadelphia College of Pharmacy and Science in 1956, and his M.D. from Jefferson Medical College in 1960. He interned at Womack Army Hospital, Fort Bragg, and then served as a preventive medicine officer in Augsburg, Germany, followed by a year of general surgery at Martin Army Hospital, Fort Benning.

In 1964, Fair came to Stanford as a resident in urology. Four years later he joined the faculty as an assistant professor and was promoted to his present position in 1972.

He is a fellow of the American College of Surgeons and certified by the American Board of Urology. Associate editor of Urology Digest, he is also a member of the ditorial board of the Journal of International Medical Research. Currently he is serving as acting head of Stanford's clinical renal transplant service.

STANFORD -- Patients will now receive fewer and less confusing bills from Stanford University Medical Center, as a result of a merger of the Hospital and Clinics patient accounting services.

The merger, which becomes effective this week, simplifies billing matters for both patients and Medical Center staff members, said Al Setton, assistant controller for patient accounting.

Formerly, since multiple bills emanated from both the Hospital and Clinics, many patients erroneously thought they were being billed twice for the same services, Setton said.

Now, all billing is handled by a Medical Center-wide patient accounting department, utilizing one computer system, one management group, and one business office.

Under the new system, patients receive a single inpatient statement, covering the regular Hospital bill and the professional fees of Stanford faculty physicians. In the past, these were billed separately by the Hospital and Clinics at different times.

Similarly, a single outpatient statement now covers all charges for emergency room services, clinic visits, and Hospital services rendered on an outpatient basis, such as radiation therapy. Previously, the Hospital issued separate bills for each emergency room and outpatient visit, while the Clinics handled charges for each clinic visit.

"The merger really uncomplicates billing matters for our patients," Setton said. "Under the old system, patients were forced to relate to two separate business offices to resolve questions regarding charges.

"Additionally, because of the overlap, insurance companies often had difficulty identifying which bills had been paid for."

Besides making things easier for patients, the merger may save the University an estimated $160,000 per year, said James Kurpius, project director. Kurpius attributed the savings to better utilization of staff and an elimination of areas of overlap.

Registration procedures have also been streamlined by the merger, Kurpius said. Outpatient registration has been centralized in one location, where patients will receive one account number for all outpatient charges. Previously, patients had to register for each type of outpatient visit and keep tabs on several different accounts.

The separate billing and registration policies dated back to the joint ownership of the Hospital by the City of Palo Alto and the University. When Stanford bought the Hospital from Palo Alto in 1968, these separate policies were continued.

Work began on the merger last June. The inpatient phase was completed October 1; the outpatient phase, April 16.

STANFORD -- A benefit golf tournament for the intensive care nurseries at Stanford University Medical Center will be held Friday, April 27, at the Oakridge Golf Course in San Jose.

Proceeds will be donated to the Medical Center to help support the treatment of critically ill infants in the nurseries, as well as ongoing research efforts concerning prematurity and serious birth defects.

The tournament is being organized by C. J. MacPherson of Santa Clara, who each year sponsors a benefit golf tournament in the Peninsula area. MacPherson's interest in the care of seriously ill infants stems from the experiences of his close friends, Mr. and Mrs. Richard Woodward of San Jose.

The Woodwards' daughter, Elizabeth Ann, was recently hospitalized in the intensive care nurseries at Stanford for treatment of a congenital heart ailment. In her honor, MacPherson decided to sponsor the "Elizabeth Ann Foundation Golf Tournament," which he plans to make an annual event.

Now over seven months old, Elizabeth Ann was born at O'Connor Hospital in San Jose on August 24, 1972 and transferred to Stanford two days later. She was hospitalized for five weeks initially and re-admitted for 11 days in February for treatment of pneumonia.

"Elizabeth Ann was born with a severe heart lesion which is presently inoperable," said Dr. Philip Sunshine, director of nurseries at Stanford. "We treated her here for several weeks, and she is currently doing remarkably well for someone with this particular problem."

Each year some 700 critically ill newborn babies from Central California and Nevada are admitted to the intensive care nurseries at Stanford, Sunshine said. About half are full-term babies with acute medical or surgical problems. The others are premature infants weighing as little as one and a half pounds. Their average length of hospitalization is six weeks.

Few young parents whose infant is treated in an intensive care nursery can pay the hospital bill without assistance, Sunshine said.

"Most insurance policies do not provide for hospitalization of newborn babies," he said. "Some 50 or 60 percent of these infants carry no insurance coverage at all, though a bill for several thousand dollars may mount up before they are ready to go home."

In the Stanford nurseries, no babies are turned away because of their parents' inability to pay the costs of treatment, Sunshine noted.

"The money raised in this golf tournament will help us continue to treat seriously ill infants and conduct research on prematurity and congenital illness," he said.

The Oakridge Golf Course is located at 225 Cottle Road in San Jose. Tee-off time for the tournament is 1:00 p.m., with cocktails and dinner immediately following.

The $30.00 entry fee includes 18 holes of golf, steak dinner with wine, and a gift package. Persons interested in participating should contact MacPherson (408:299-3242) or the Premature Infants Research Center at Stanford (415: 321-1200, ext. 5445).

STANFORD -- Secretary of the Interior Rogers C. B. Morton today (Friday, April 13) completed seven weeks of radiation therapy at Stanford University Medical Center for treatment of an early-stage malignancy of the prostate.

"Secretary Morton has responded very well to the treatment, and there is every reason to be optimistic about his condition," said Dr. Malcolm A. Bagshaw, chairman of the Department of Radiology at Stanford.

Morton, 58, checked in at Stanford on February 20 as an outpatient. The prostate malignancy had been discovered during a routine physical examination by his personal physician.

During his treatment at Stanford, the Secretary was ambulatory and maintained a small office at the U.S. Geological Survey in Menlo Park.

He is expected to return to Washington, D.C. after a brief recuperation period.

STANFORD -- An experimental class for pre-school children with speech and language problems will be launched this fall by the Communication and Learning Disorders Center at Stanford University School of Medicine.

Supported by a $10,000 grant from the Luke B. Hancock Foundation of Menlo Park, the class will include 10 to 12 children ranging in age from three-and-a-half to five-and-a-half years, said Dr. Kathryn Beadle, director of the Center.

The purpose of the class, she said, will be to increase and improve the children's verbal language skills so they will be better prepared to enter school.

"Children with developmental speech and language disorders represent one of the high risk groups for eventual learning disabilities," Dr. Beadle said. "Because of this, we believe our program can make a valuable contribution to the prevention of such academic learning problems."

The program will provide intensive work on establishing perceptual and motor skills, as well as developing linguistic areas, she said. Emphasis will be placed on teaching the children to use language and speech to organize and integrate their experiences.

The class will be directed by a language pathologist and special education teacher, with consultation from a physical education instructor and an occupational therapist. It will run five mornings a week for the full nine-month academic year.

To determine the effectiveness of the program, the children will be evaluated in several ways both before the class begins and again after it concludes, Dr. Beadle said. If it is proven effective, and additional funding can be obtained, the class may be established on a permanent basis.

In a companion grant, the center received $4,000 from the Hancock Foundation to establish a closed circuit television and videotape system. The system will be used for observation of patients and evaluation of clinical procedures in several programs for both adults and children. Tapes will also be used for a variety of teaching purposes.

The Communication and Learning Disorders Center is presently located at 400 Willow Road, north of Stanford Hospital and across from the Stanford Shopping Center.

The Luke B. Hancock Foundation was organized 25 years ago. Hancock, a specialist in oil production, died in 1961.

STANFORD -- A research project to evaluate the long-term effects of weightlessness on a colony of living human cells aboard Skylab has been postponed until later this year, the project's co-investigator said Wednesday (May 30).

Dr. Leonard Hayflick, professor of medical microbiology at the Stanford University School of Medicine, said the cell experiment was among several dropped from the mission to make room for repair equipment aboard the command ship.

The equipment was used by astronauts to perform repair work outside the crippled orbiting space station. It included an emergency parasol used to replace Skylab's damaged meteoroid and heat shield which had caused temperatures inside the ship to soar dramatically.

The human cells were to have been stored in tiny glass chambers and flown aboard the command p to Skylab. They would have been returned to earth so that scientists could learn what effect a month of zero gravity has on their growth, reproduction and genetics.

The cells would have been maintained in tissue culture and their growth and movements in space would have been recorded photographically.

Hayflick said NASA officials have told him that the cells will be sent aloft when two other teams of astronauts slated to spend 56 days in orbit later this year might be able to live and work aboard Skylab.

The frozen human cells have been preserved at a Stanford cell bank for 11 years. They were picked for this experiment because they have been studied extensively and their characteristics are well known.

STANFORD -- Dr. Merlin K. DuVal, vice president for Health Sciences at the University of Arizona and former assistant secretary for health and scientific affairs at HEW in Washington, will be the keynote speaker at the annual alumni reunion of the Stanford University School of Medicine Saturday, June 2.

Dr. DuVal will speak on "Health and Public Policy" at 1:30 p.m. in the Cooper Courtyard of the Medical School.

The 51-year-old medical educator served as an assistant secretary in the Department of Health, Education and Welfare from 1971-72. He holds an M.D. degree from Cornell University Medical College, was professor of surgery at the University of Oklahoma School of Medicine from 1961 to 1964, and dean of the University of Arizona College of Medicine from 1964 to 1971.

In addition to his surgical contributions, Dr. DuVal is considered a leader in medical education. His writings in recent years have covered many other topics, including the need of bridging the gap between medicine and the law, health manpower, development of quality standards for health care, rural health, and public health policy. He is currently chairman of the liaison committee of the joint task force on medical education of the American Medical Association and the Association of American Medical Colleges.

Morning sessions at the day-long alumni reunion will begin at 9:45 a.m. in Room M106 of the Medical School. They will include presentations on new engineering concepts in medicine and the implications for the practicing physician.

The program will be chaired by Dr. Donald C. Harrison, William G. Irwin Professor of Medicine and head of the Division of Cardiology.

Among the topics are "Integrated Circuit Technology--'Sight for the Blind,' ", "Computer and Ultrasound Methods for Measuring Cardiac Function," "Cardiac Biopsy--Application of a New Method for Diagnosing Heart Disease," "The Pharmacology of Anti-arrhythmic Drugs for Prevention of Sudden Death," and "Outpatient Heart Monitoring."

The afternoon session at 3 p.m. will feature Dr. L. Martin Griffin, a Stanford alumnus, who will speak on "Springtime in Nepal." In addition to his practice in internal medicine in Marin County, Dr. Griffin has distinguished himself as a naturalist and environmentalist. In the past four years, he has scouted and led expeditions into the Himalayas to observe and photograph animal and plant life. He was recently elected to the board of directors of the Marin Municipal Water District.

STANFORD -- Dr. Robert J. Glaser, president of the Henry J. Kaiser Foundation and visiting professor of medicine at the Stanford University School of Medicine, will be honored as "a distinguished American educator" May 29, Temple University announced Friday (May 25).

He will be awarded an honorary Doctor of Science degree at Temple University's commencement exercises.

Glaser, a Harvard University graduate, has had a distinguished career in medicine starting in 1945. He was associate dean of the Medical School at Washington University for two years; vice president for medical affairs at the University of Colorado for four years; vice president for medical affairs and dean of the School of Medicine at Stanford University for five years, and is past president of the Association of American Medical Colleges.

He is a member of the board of medicine of the National Academy of Sciences and has served on numerous private and governmental committees.

Glaser also served a stint as acting president of Stanford before he left to become vice president of the Commonwealth Fund of New York.

Others honored by Temple University include Dr. Paul A. Freund, a Harvard Law School professor, and United States Senator Edward W. Brooke (R-Mass.).

STANFORD -- Have you ever tried a steak shake, or an apple pie drink? They may not appeal to many people, but to anyone on a liquid diet, they taste delicious.

So claims Wilma King. The laboratory assistant in the Department of Genetics at Stanford University School of Medicine has written a recipe booklet for people who can't chew their food. Entitled Blend and Mend, it contains meals that can be liquified to milkshake consistency and drunk through a straw.

The suggestions are the results of the author's own culinary experiments while recuperating from a jawbone graft performed at Stanford in 1970. For almost four months her jaw was wired shut with space enough for a straw where a tooth was knocked out. She was restricted to a liquid diet for a year.

"I was starving on the tasteless hospital diet. When I got home, I decided I could whip up much better meals," Mrs. King said. Now she is sharing her recipes with others on similar diets. The approximate number of calories per meal is included to help readers plan their menus.

Mrs. King admitted that the dishes may not look like what people are used to, but pointed out that they provide variety as well as nourishment. For a dinner of roast beef and mashed potatoes that is 670 calories, she suggests: a 3-ounce serving of roast beef, 1/2 cup mashed potatoes, 1/2 cup gravy and 1 cup beef bouillon. Her instructions are to process meat in the blender two cycles at chop, then add remaining ingredients and process one cycle at stir, two cycles at blend.

Perhaps her most helpful selection is an original poem called "Fears and Tears" which she offers in the book's introduction. It calls for: "1 cup happiness, 1/2 cup fear, 1 cup patience, 1/4 cup tears, 1 cup time, dash of a year; put into blender fears and tears, process three cycles at grind or until they disappear; add the remaining ingredients, process one cycle at mix, two cycles at blend, or until your good health reappears!"

The author also urges readers not to stay at home because of their problem. "Cooks and waitresses in restaurants...(will) blend things to your order and laugh with you---not at you--for your courage."

-more-

She, herself, has a lot of spirit and courage. Two weeks after she was discharged from the Hospital, she was back on the job she has held here since 1962. "I couldn't sit still at home," she explained. "My head was bandaged, so I bought myself a wig and came back to work, bandages and all!"

Actually, Mrs. King hasn't had a good piece of steak since 1965, when she first broke her jaw. It was wired together, but when the wires loosened in 1970, the bone had deteriorated. Her lower jaw was replaced with part of her hip bone in an operation performed by Dr. Donald Laub, associate professor of surgery. The next year, just as her recovery was considered complete, she smashed her new jaw in a minor car accident. Further surgery was ruled out and she will probably be on a soft diet the rest of her life, although she is not confined solely to liquids.

Publishing expenses for the 24-page booklet came out of the author's pocket, but she hopes to recoup them from sales. However, she noted that her aim was not to make money. "I just want to get the message out for the benefit of other people on liquid diets," she said. At least 10 percent of the book's earnings will go to Laub and Project Concern for the plastic and reconstructive surgery they help provide to underprivileged Central American children. She would also like to have enough to contribute to other worthy causes.

The booklet is more popular than she expected, commented Mrs. King, who does the advertising from her home in Mountain View with the help of her husband Donald. She has sold the book to several local stores, including the Stanford bookstores and the Hospital gift shop, and has filled many individual requests from patients and physicians. It sells for $1.95 a copy.

STANFORD -- A five-year, federal grant for $2,569,311 has been awarded to Stanford University School of Medicine for continued research in human heart transplantation.

The grant, funded by the National Heart and Lung Institute (NHLI), is the largest in the history of heart transplant research, according to NHLI officials. It was announced today (May 22) by Dr. Theodore Cooper, director of the NHLI, and Dr. Clayton Rich, dean of the School of Medicine and vice president for medical affairs at Stanford.

"This award will enable us to continue to explore and evaluate the clinical application of heart transplantation," said Dr. Eugene Dong, Jr., principle investigator and associate professor of surgery at Stanford.

The primary goal of the research effort, Dong said, will be further refinement of the post-operative treatment of transplant patients. He said the program will focus on four main areas:

--improvement of the diagnosis of cardiac rejection;

--development of new methods to treat rejection;

--prevention of some of the long-term consequences of immunosuppressive drugs (drugs which check the body's immune or defense system); and

--utilization of biomedical engineering to evaluate heart function in transplant patients.

Rejection of the transplanted heart by the body's immune system remains the main obstacle to more successful heart transplantation. For years, researchers have sought better methods to detect and treat rejection in its earliest stages.

"We hope to determine the changes in the body's immune system which occur early in a rejection episode," Dong said. "If we can spot these changes before irreversible damage is done to the heart, we may be able to treat rejection more specifically and effectively."

In addition to investigating new therapeutic drugs to combat rejection, the Stanford researchers plan to study more precisely how transplant patients respond to currently-used agents.

-more-

"We need to find out why two patients receiving the same drug treatment respond very differently, and why some patients require less drug therapy than others," Dong said.

For long-term transplant survivors, one of the consequences of prolonged drug treatment has been the speeded-up development of atherosclerosis.

"We've noted in some of our early patients that there is a recurrence of the original heart disease in an accelerated fashion," Dong said. "Our current, still inconclusive data, indicate that through diet control, exercise, and anti-clotting drugs, this may be preventable."

The final area of research is related to evaluation of cardiac function in transplant patients.

"Unfortunately, many current methods are invasive, with a small but definite degree of risk," Dong said. "Our aim is to evaluate cardiac function using safe, non-invasive, non-painful, and non-toxic techniques."

These techniques include computerized analysis of electrocardiograms and echocardiograms (measurement of the heart's rate of motion, chamber size and wall thickness, using high frequency sound waves).

Co-investigators with Dong will be Drs. Norman E. Shumway, professor and head of the division of cardiovascular surgery; Edward B. Stinson, assistant professor of surgery, and John S. Schroeder, assistant professor of cardiology.

After over a decade of animal experimentation by Shumway, Dong, and their associates, the first human heart transplant at Stanford was performed in January of 1968. Since that time, 58 patients have received new hearts at Stanford; 22 are now living.

"The new grant reflects the continuing progress which has been made in heart transplantation over the past five years," Dong said. "The funds provide for continuance of the essential elements of our program, but due to the continuing restriction of government support, several important projects had to be cut."

Previously, Stanford had received $813,000 from NHLI over the past three years for clinical transplantation. Animal experimentation will continue under another ongoing grant.

Dong, a native of Watsonville, California, obtained his M.D. from the University of California, San Francisco, in 1959. The 40-year-old surgeon served his internship at Bellvue Hospital in New York and his residency in cardiovascular surgery at Stanford. He has held research fellowships from the American Heart Association and the United States Public Health Service. From 1966-71, he was an Established Investigator of the American Heart Association.

STANFORD -- Young women whose mothers received stilbestrol--a synthetic form of estrogen--during pregnancy are being sought by Stanford University gynecologists for a study of the relationship between exposure to this hormone in the uterus and development of a very rare vaginal cancer.

The relation of stilbestrol to cancer in young women was first suspected in 1971, when two physicians at the Massachusetts General Hospital found the extremely rare cancer of the vagina in seven young women whose mothers had received stilbestrol during their pregnancy.

Documented incidence of stilbestrol-linked cancer in humans, however, is extremely small, according to Dr. Eugene Sandberg. Emphasizing that there is no cause for alarm, the associate professor of gynecology and obstetrics at the School of Medicine explained:

"Stilbestrol was administered to pregnant women with threatened or frequent miscarriage or certain conditions such as diabetes.

At least 200,000 female offspring (perhaps far more) were exposed to the hormone and less than 100 cases of cancer have been reported to date."

Nevertheless, Sandberg feels that all women whose mothers were treated with stilbestrol should be regularly examined. He will direct a clinic at Stanford where these women will receive free examinations.

Minor, non-malignant changes have also been observed in the vaginal wall and cervix of these young women, said Sandberg. Many of them seen so far have unique anatomical variations of the cervix. Some also have vaginal adenosis, an unusual condition in which the vaginal wall contains glands ordinarily seen only in the cervix. These structures are generally benign and often go unnoticed in the healthy female, noted Sandberg, author of several publications on adenosis.

"It is probable that stilbestrol modifies embryological tissues so that they develop these unusual changes," explained Sandberg. "While the variations are usually benign, they could have a malignant predisposition that would sensitize a small percentage of these women to the development of cancer."

Sandberg believes that women with such tissue abnormalities should be checked with regularity. He and Dr. Sue Massey, staff gynecologist at Cowell Student Health Center on campus, are examining these changes. The women will be followed free of charge at the new clinic which will be held on Wednesday mornings in the Gynecology Clinic at Stanford Medical Center.

There is no indication that stilbestrol has any harmful effect on the mothers who received it or on other women who receive it as medication, stressed Sandberg. The only effect to be concerned about, he said, "appears to be on embryological tissues during the third or fourth month of intrauterine development."

STANFORD--Local clergy add a personal touch to patient care at Stanford University Hospital.

In an age of technology and specialization, patient care requires more than medical excellence alone, explained Paul Hofmann, deputy director of Stanford University Hospital.

"The hospitalized person has spiritual and emotional needs as well as physical ones that must be met," he said.

The administration is seeking funds to support a full-time chaplaincy program. Meanwhile, Hofmann is working closely with ministers, priests and rabbis in the community to extend pastoral services for patients at Stanford.

Clergy of the Catholic, Jewish and Prostestant religions have volunteered to be available to Hospital patients and staff on a 24-hour basis. Members of each denomination rotate being "on call" for a particular period. If emergencies arise, the nurse on the unit can contact a clergyman of the patient's faith.

The role of the hospital chaplain is often underestimated, according to Hofmann, yet he can make a significiant contribution as a member of the health care team. Hofmann explained:

"Admission to a hospital is frequently a depersonalizing experience--the patient is stripped of belongings, identified by a bracelet and rendered dependent on many unfamiliar faces in a strange environment.

"For this reason, it is important to have someone on the team whose major responsibility is the emotions and responses of the patient as a human being."

A specialist in caring, the chaplain recognizes and understands the feelings of depression, fear or loneliness that a patient may have, and can help the individual deal with them.

The deputy director has established an advisory committee of representative clergy and Hospital staff members to explore the ways in which the two groups can work together. Seminars on topics of mutual concern, such as caring for the terminally ill patient, are also being planned.

A patient admitted to Stanford Hospital can now complete a card indicating that he would like a visit from a minister. If the patient knows a clergyman in the area, that person is notified by a member of the Medical Center Auxiliary. When a patient wishes a visit, but does not specify anyone, arrangements are made with a clergyman of his faith in the community. The services of the University chaplain, the Reverend Robert Minto, are also used.

-more-

Previously, the system for pastoral care at Stanford was less comprehensive, Hofmann noted. The local parish of the Roman Catholic Church had its own schedule to cover Catholic patients in the Hospital, but recently the Reverend Raymond Dunn was appointed full-time Catholic chaplain. Individual Jewish and Protestant clergy continued to make visits as often as possible. The administrator said that all the clergy have supported the new organization with enthusiasm.

Hofmann, who helped develop a hospital chaplaincy program in southern California before coming here last year, hopes that funds for a full-time chaplain can be found by the end of this year. An outside source is needed, he explained, because the Hospital operates almost solely on income from patient charges, and the existing budget does not contain resources for this purpose. The chaplaincy program is a service that would meet several needs.

"Although he has an obligation to all faiths," said Hofmann, "the full-time chaplain would complement the local clergy." He would work with them to organize seminars and provide appropriate spiritual resources for patients and their families.

Another responsibility of the chaplain would be to develop a program at Stanford to train other pastors and theological students. Clergy who complete clinical courses under the supervision of a certified person at an accredited institution are qualified as hospital chaplains by the Association for Clinical Pastoral Education.

In addition to ministering to the needs of patients and training clergy, the chaplain could assist and counsel the medical and nursing staff. A staff member who needs advice on providing more effective support to a patient would be able to consult with the chaplain.

STANFORD -- Dr. Edward B. Stinson, assistant professor of surgery at Stanford University School of Medicine, has been awarded a five-year Established Investigatorship by the American Heart Association.

The award, effective July 1, was announced today (May 16) by Dr. Harold Hubis, chairman of the Bay Area Heart Research Committee.

A member of Stanford's heart transplant team, Stinson will receive $134,000 over the next five years to support a portion of his salary as well as his clinical and laboratory research on heart transplantation.

He plans to investigate new methods for the early diagnosis of rejection of the transplanted heart. He will also initiate new studies of human and dog transplant recipients to more effectively evaluate the functioning of the transplanted organ.

More sensitive methods to detect rejection are needed, Stinson said, so that preventive action can be taken before irreversible damage is done to the heart.

By focusing on changes in the body's immune or defense system which are known to occur early in a rejection episode, he hopes to define new indications of impending rejection, he said.

The 34-year-old San Diego native obtained his A.B. (1960) and M.D. degrees (1965) from Stanford. After internship at Hennepin County General Hospital in Minneapolis, he returned to Stanford and was trained as a cardiovascular surgeon by Dr. Norman E. Shumway.

He has held research fellowships from the United States Public Health Service (USPHS), the Bay Area Heart Research Committee of the American Heart Association, and the Bank of America-Giannini Foundation.

With the exception of a stint at the National Institutes of Health from 1970-72, Stinson has been a member of the heart transplant team at Stanford since the first transplant was performed at the Hospital in January of 1968. In all, 57 patients have received new hearts at Stanford; 21 are currently surviving.

This year, 29 scientists were awarded Established Investigatorships by the American Heart Association.

Each year the AHA makes these five-year awards to a small number of "individuals of proven superiority and originality who have demonstrated qualifications and motivation for careers in research."

Previous winners at Stanford include cardiovascular surgeons Shumway, Eugene Dong, Jr., Edward Hurley and William Angell.

STANFORD -- Dr. Robley C. Williams, noted biophysicist, will deliver the second annual Edwin W. Schultz Memorial Lecture, Friday, May 18 at Stanford University School of Medicine.

He will present some of his recent work in a talk entitled "Observations on the Structure of Viruses." It will begin at 4:00 p.m. in Room M106 at the Medical School.

A member of the faculty at the University of California, Berkeley, since 1950, Dr. Williams is professor of molecular biology and associate director of the virus laboratory at Berkeley. From 1964 until 1969 he was the first chairman of the newly created Department of Molecular Biology.

His research interest for years has been in electron microscopy. He has been instrumental in the development of new techniques that enable scientists to discern more detailed structure of viruses and enzymes than previously seen with the electron microscope.

Dr. Williams is also investigating how tobacco mosaic virus (TMV) -- which multiplies in tobacco plants -- is assembled from its protein and nucleic acid portions. In 1955, he and Dr. Heinz Fraenkel-Conrat were the first to break down the rod-shaped TMV particles into their components and then mix the components together again to form new particles, identical to the originals and capable of infecting the tobacco leaf.

In the past, Dr. Williams worked with other optical instruments. He has done spectroscopy studies of hydrogen and of surface temperature of stars.

Born in Santa Rosa, he is an alumnus of Cornell University, receiving his A.B. in 1931 and his Ph.D. in physics in 1935. For the next 15 years he was at the University of Michigan, first in the astronomy department, and then as professor of physics.

He joined the Berkeley faculty in 1950 as professor of biophysics in the Department of Biochemistry. He later became professor of virology until he received his present title in 1964.

The Schultz lectureship, established last year, honors Dr. Edwin W. Schultz, who was chairman of the Department of Bacteriology and Experimental Pathology (now Medical Microbiology) for 33 years.

An educator and a researcher at Stanford since 1919, Dr. Schultz served as department head from 1920 until his retirement in 1953. His pioneering studies of poliomyelitis are well known in the field of virology.

Following his retirement from Stanford, Dr. Schultz was director of an international medical training project at the University of Indonesia until 1960. He subsequently did research at the National Institutes of Health and at the Regional Primate Research Center in Oregon. In 1971, he died at the age of 83 after a long illness.

STANFORD -- Dr. Ruth T. Gross, chief of pediatrics at Mount Zion Hospital and Medical Center in San Francisco, has been appointed professor of pediatrics and an associate dean for student affairs at the Stanford University School of Medicine.

Her appointment, effective July 1, was announced today by Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

Since 1966, Dr. Gross developed and directed several successful programs in community health at Mount Zion Hospital and Medical Center. They included a comprehensive care program for children and youth, supportive programs for adolescent parents and their infants, and the first federally funded infant day care program in the Bay Area.

In her new position, according to Dr. Irving Schulman, chairman of the department of pediatrics, Dr. Gross will serve as coordinator of the clinical training in child health for medical students at Stanford and its affiliated hospitals. She will serve as attending pediatrician in patient care on the wards and outpatient pediatric department, and will engage in research to identify new types of health services for children which should be established at Stanford.

As an associate dean for student affairs, Dr. Gross will work closely with Associate Deans John P. Steward, M.D. and William P. Creger, M.D. on the development of the clinical aspects of medical student training, Dean Rich said.

Dr. Gross' arrival at Stanford will mark her return to the Stanford Medical School. She was a member of the pediatric faculty from 1950 to 1959, and served a two-year stint as acting pediatric chairman when the School was located in San Francisco.

A graduate of Barnard College, Columbia University, she received her medical degree from the Columbia University College of Physicians and Surgeons in 1944.

Dr. Gross has held academic appointments at Radcliffe Infirmary, Oxford, England, and was a professor of pediatrics and co-director of the Division of Human Genetics at Albert Einstein College of Medicine when she joined Mount Zion Hospital in 1966. She also serves as a clinical professor of pediatrics at the University of California in San Francisco.

Her research has included various aspects of drug-induced hemolytic anemia, metabolic aspects of disease in the newborn and premature, new approaches to health care delivery, and development of the problem-oriented medical record.

STANFORD -- Dr. Donald C. Harrison, professor and head of the division of cardiology, has been named the first holder of the William G. Irwin Professorship at the Stanford University School of Medicine.

The endowed professorship, made possible by gifts from the William G. Irwin Charity Foundation of San Francisco, is awarded to an expert in the diagnosis and treatment of heart disease. The professorship supports the holder's salary and part of his teaching and research work.

Dr. Harrison has been a member of the Stanford faculty since 1964. He is known as an innovative academician who combines an interest in clinical research with a deep concern for patient care.

When, at the age of 32, Dr. Harrison became chief of cardiology at Stanford in 1967, he was one of the youngest men ever to become head of a major cardiology unit.

Since then, his two objectives have been to develop training for young cardiologists, and programs for both investigative and clinical cardiology.

The two major areas for which Stanford's division of cardiology has become nationally known are Dr.Harrison's studies with anti-arrhythmic drugs, and development of heart monitoring devices that may help to prevent sudden death.

A 1958 graduate of the Medical College of Alabama, Dr. Harrison took additional training at the Peter Bent Brigham Hospital in Boston. He also did research at Harvard Medical School and the National Heart and Lung Institute, Bethesda, Md.

The 39-year-old cardiologist is married and lives with his wife and three children in Los Altos, California.

FOR IMMEDIATE RELEASE

STANFORD — Dr. David A. Hamburg, professor of psychiatry, has been named the first holder of the Reed-Hodgson professorship in human biology at Stanford.

The Reed-Hodgson chair was established this year with gifts from Richard Hodgson and his wife, the former Geraldine Coursen Reed, as well as with funds from a Ford Foundation grant to the human biology program.

Mr. and Mrs. Hodgson are Stanford alumni. He is a group vice-president of International Telephone and Telegraph Corporation in New York. Mrs. Hodgson is a former vice-president of Ellington and Company, a New York advertising agency.

The professorship is the second to be established in the interdisciplinary Human Biology Program, one of Stanford's three most popular undergraduate majors, which Dr. Hamburg helped establish in 1969.

A member of the National Academy of Sciences, Dr. Hamburg served as chairman of the Department of Psychiatry for 11 years. He stepped down from his administrative responsibilities last year to pursue new programs of education and research.

A leading authority in the study of hormonal responses to psychological stress, Dr. Hamburg has been instrumental in developing the Laboratory of Stress and Conflict.

The laboratory is an interdisciplinary faculty project organized by Dr. Hamburg to develop courses and research projects on behavior under stress. It involves work with patients and also research on chimpanzees at the forthcoming Stanford Primate Facility and in Africa.

In the Human Biology Program, faculty members from the Medical School and the biological and social sciences team to present a comprehensive view of man from a life sciences perspective.

Dr. Hamburg also aided in planning the Program of Science, Technology, and Society in which a group of scholars will come to the Center for Advanced Study in the Behavioral Sciences each year to study the social impact of scientific and technological developments. The Center, an independent institution, is located on the hills behind the Stanford campus.

Dr. Hamburg, 46, came to Stanford in 1961 from the National Institutes of Health, where he was chief of the adult psychiatry branch. Under his leadership, Stanford's Psychiatry Department has earned international recognition, particularly for its scientific approach to psychiatric problems.

He is a 1947 graduate of the Indiana University School of Medicine and received his professional training at Michael Reese Hospital in Chicago and Yale University.

Dr. Hamburg and his wife, Beatrix, also a faculty member and psychiatrist, live on the Stanford campus. They are the parents of two children.

STANFORD -- A night psychiatry clinic will be established this month at Stanford University Medical Center.

The new clinic, which opens Monday, May 14, hopefully will make psychiatric services more accessible and convenient for patients in the area, said Dr. Floyd Estess, director of Stanford's psychiatry clinics.

"Mental health services often require more time for each individual visit and for the duration of treatment than other types of health care," Estess said. "But many people in need of these services have job commitments and can't take off the necessary time during the day."

Initially, the clinic will operate Monday and Wednesday nights from 5:30 to 9:30 by appointment only.

"We'll start with two nights per week to see if there is sufficient community need for such services," Estess said. "If necessary, we are prepared to expand the schedule."

The clinic will be staffed by Stanford psychiatrists, psychologists, and psychiatric social workers. It will offer diagnostic studies, as well as individual, couple, and group therapy.

Fees will be charged according to ability to pay, Estess noted. However, there are minimal fees for each of the various services offered, he said.

The Stanford psychiatry clinics offer a full range of psychiatric services, including such highly specialized areas as sleep disorders and sexual and marital problems. Over 16,000 patient visits are made annually to the clinics, housed in an 18-month-old building located next to the Medical Center complex.

STANFORD--All four children of the David Costello family of Santa Rosa, California, are recovering today after open heart surgery at Stanford University Hospital.

The children--David, 18; Richard, 15; Kevin, 13; and Karen, 4--were born with a congenital heart ailment known as atrial septal defect. Today, they were operated on by surgical teams headed by Drs. Norman Shumway and Edward Stinson, two members of Stanford's heart transplant team.

"The surgery went very well, with no complications," Dr. Stinson said. "The children should recover quickly and be able to lead more active lives."

"I'm tremendously relieved," Mrs. Costello said. "I've had about four hours of sleep in the last week.

"Really, I'd like to thank the world. Thanks for the blood donations, all the letters, and the support."

The Costello children were born with a hole in the muscular wall (septum) between the heart's upper chambers (atria). Leakage of blood through the holes resulted in improper blood flow and an imbalance in the pressures within the heart. Because of this, insufficient oxygen-carrying blood was pumped to the body tissues.

Like other patients with atrial septal defect, the Costellos have tired easily and faced some restrictions in their physical activity.

The Stanford surgical teams included Drs. Shumway, Stinson, Philip Caves, Jefferson Hollingsworth, and Wally Buch. The surgeons said the defect is not an uncommon one, and the surgical procedure is "fairly routine."

— more —

Smaller holes in the septum are sewn up; larger holes are patched with tissue from the pericardium, the membraneous sac enveloping the heart. Two of the Costello children, Karen and Kevin, had holes small enough to be sewn; the holes in David's and Richard's septums, roughly the size of a silver dollar, were patched. In all four cases the operation required a little over two hours.

The children will spend the next two or three days in the Hospital's intensive care unit. After an additional three to five days in the pediatrics ward, they will be discharged.

Within a month or two, they should be able to lead more active lives than they did previously, Stinson said.

STANFORD--The Henry J. Kaiser Family Foundation Thursday (June 1) announced a $50,000 grant to the Stanford University School of Medicine to help support its training program in biochemistry threatened by sudden cutbacks in federal training grants.

In a letter to Dr. Paul Berg, chairman of the biochemistry department, Dr. Robert J. Glaser, president of the Foundation, said the grant was made to emphasize the conviction that there must continue to be a strong research support in the basic medical sciences.

"In spite of its present focus on medical care, the Kaiser Foundation assigns a high priority to preserving centers of excellence for the training of basic medical scientists," Glaser said.

Since 1959, Stanford's biochemistry department has trained scores of graduate students, postdoctoral fellows, medical students, and senior investigators. They have made careers not only in biochemistry, but also in chemistry, microbiology, biophysics, genetics, and the clinical sciences.

The department has gained international distinction for its work in genetic chemistry, and its former chairman, Dr. Arthur Kornberg, won a Nobel Prize in medicine.

The department's funding problems began earlier this year when the National Institutes of Health told the nation's medical schools it was phasing out all training and fellowship programs.

The Kaiser foundation grant, according to Berg, will support the research training of graduate students to be admitted during the next few years. Without such support graduate student admissions would have to be sharply curtailed.

The biochemistry department also trains more than 40 postdoctoral fellows and senior basic scientists. Federal funding for support of research fellows has also been eliminated. Dr. Berg indicated that additional support is still needed for the remaining program as well.

Dean Clayton Rich of the School of Medicine said the commitment on the part of a major foundation to the training of basic medical scientists is a very important symbolic step at a time when federal research support is being cut without real understanding of the long-term consequences to the nation's medical schools.

STANFORD--"Why can't a woman be more like a man?"

That question will be addressed Wednesday (June 27) by Dr. Estelle R. Ramey, professor of physiology and biophysics at Georgetown University School of Medicine, when she delivers the first Katharine McCormick Lecture at Stanford University School of Medicine.

The lecture, sponsored by the Professional Women of Stanford Medical School, will begin at 4 p.m. in Room M106. It will be open to the public free of charge.

Dr. Ramey is currently president of the Association of Women in Science (AWIS) and vice president of the Women's Equity League.

Last year she represented AWIS in a controversy over an anatomy textbook which the organization felt was denigrative to women. She was instrumental in having the text removed from bookstores and taken off the market. In the last few years, she has authored several articles related to the women's movement.

Dr. Ramey received her Ph.D. from the University of Chicago, where she was a Mergler Scholar. Her research has focused on the relationship between adrenal cortical hormones and the central nervous system in the regulation of blood vessel and metabolic responses to stress.

The author of two books and over 70 scientific papers, she has been a recent lecturer at several government agencies, including Distinguished Lecturer of the State Department. A member of the major professional societies, she is also a director of the Washington Heart Association.

The Professional Women at Stanford named their lecture in honor of the late Katharine D. McCormick, who left a bequest of $5 million to Stanford in 1969 to aid programs of the School of Medicine. The organization, composed primarily of women M.D.'s and Ph. D.'s, was formed four years ago "to promote development of opportunities for women in the medical sciences."

STANFORD--A junior faculty member at Stanford University School of Medicine has developed a computerized medical record. A resident in surgery has designed a new course for medical students at Stanford and an intern is writing a book on the use of illness.

These young physicians are the beginning of a new breed. They are clinicians specializing in the skills needed to meet emerging problems in health care delivery.

The Medical School has been awarded $96,000 from the Robert Wood Johnson Foundation Clinical Scholar Program to continue training such doctors for another year. Effective July 1, the grant will support six clinical scholars investigating economic, educational, political or social aspects of medicine.

"There is a need for people with expertise in clinical medicine and the non-biological disciplines related to medicine," said Dr. Halsted Holman, professor of medicine and director of the Clinical Scholar Program at Stanford.

The scholars will do individual research in non-medical areas of health in a manner similar to the physician scientist.

Holman expects clinical scholars to help bridge the gap between medicine and the community. They would coordinate and staff community health care programs and clinics, develop and teach new types of courses in both clinical medicine and the non-biological disciplines, or assist government and public service agencies on health care policy planning.

The Johnson Foundation program is based on pilot projects developed by Stanford and four other medical schools over the last three years. Funds were provided by the Carnegie Corporation and the Commonwealth Fund. They were used at Stanford to support three scholars and to help develop new programs that would provide a basis for training future clinical scholars.

As Stanford's first clinical scholar, Dr. James Fries, assistant professor of medicine, began developing a computerized medical record. The patient chart, now being adapted for use in the Medical Center, saves time for physicians and aids them in making clinical decisions.

Information is recorded on flow sheets to display the patient's medical history in chronological order. Clinical data fed into the computer can be used to review a patient's status or to study the course of, and response to, therapy of similar patients.

Former scholar Dr. Edwin Alderman, assistant professor of medicine, designed data forms for handling cardiology information. The third participant in the experimental project, Dr. Raymond LaSure, assistant professor of medicine, will continue as a clinical scholar in the new program. He is concerned with assessing the quality of health care and meeting the medical needs of the poor.

"The other five doctors who will begin training in July as clinical scholars bring with them diverse interests and considerable experience," noted Holman.

-more-

FILE COPY

222--Clinical Scholars

One of the incoming scholars is Dr. Douglas Rund, a resident in surgery. He is interested in clinical education and will explore ways to maximize the clinical experience for students.

When he was a medical student at Stanford two years ago, Rund worked with the clinical scholar program to initiate a student teaching course in physical diagnosis. The course was taught by senior medical students for first year students who wanted to relate clinical problems to their preclinical subjects before the second or third year when clinical courses are usually given.

Rund, who intends to pursue a career in general surgery as well as academic medicine, would like to see surgeons more involved in the economics of health care. He thinks their involvement would add a new dimension to medical problems.

Another new scholar is Dr. Howard Waitzkin, an intern at Stanford who in addition to an M.D., has a Ph.D. in sociology. He is working on a book about the roles of illness, based on research he began as a student in Boston and continued at Stanford. In the book, he discusses shortcomings in the present health care system and suggests that local communities have more control over medical care.

Waitzkin will also study information withholding and how patients find out about what's wrong with them. In addition, he will work part-time at the United Farm Workers clinic in Salinas.

The other scholars scheduled to arrive at Stanford are Drs. Michael Eliastam, who also has a Master's degree in public administration; Lawrence Horowitz, who has been a member of Senator Edward Kennedy's staff; and Jeffrey Weisberg who has been doing emergency medical practice.

An interdepartmental committee from the Medical School will supervise the clinical scholar program, which will draw on faculty from throughout the University. Scholars will work together in seminars and individually on their own projects with a faculty adviser.

The Johnson Foundation announced recently it will award a total of $5.9 million to at least eight medical schools for training clinical scholars over the next four years. Programs at the five original institutions--Stanford, Case Western Reserve, Duke, Johns Hopkins and McGill--have all been funded through June, 1974. Then the schools will apply with other schools for another three years of support.

In the future, Stanford hopes to integrate its program with the University of California, San Francisco Medical School. "By combining the resources of the two schools," said Holman, "we would avoid duplication and provide greater breadth in our Clinical Scholar Program."

EDITORS: The following story sent Business Wire 6/20/73.

STANFORD--The first class of physician's assistants trained at Stanford University Medical Center will graduate this Friday, June 22, in ceremonies beginning at 2 p.m. in the Medical Center's Grant Courtyard.

The 16 students completed a two-year training program that will enable them to aid community physicians in the delivery of primary health care.

"Our main objective is to place graduates with doctors in areas where medical services are needed," said Kees Ploeg, associate director of the program. "Twelve members of the first class have already found employment, and all of them will be working in underserved rural areas of California."

Following graduation, the physician's assistants can practice with interim certification from the State Board of Medical Examiners until December, when they will take the state and national certifying examinations.

The Stanford graduating class, including nine former Army medics, six registered nurses, and one Bachelor's degree recipient, will be only the second group of physician's assistants ever to graduate in California. The first, trained at Charles R. Drew Postgraduate Medical School in Watts and U.C.L.A., graduated May 25.

The programs based at Stanford and Drew are the only two which have been established in California since the state enabling legislation was passed in 1970.

Stanford's two-year program, co-sponsored by Foothill Junior College in Los Altos Hills, consists of classroom instruction, rotation through clinical services at Stanford or an affiliated institution, and practice with a community physician.

During the first year, students take basic science courses at Foothill to fulfill requirements for an Associate of Science degree. The second year begins with four months of classes at Stanford focusing on common medical problems.

After initial clinical experience is gained through participating in rotations, the students conclude the program by assisting a community physician for 12 weeks.

6/20/73

-more-

222--Physician's Assistants Graduate

Although the physician's assistants cannot make a diagnosis or prescribe treatment without consultation from a doctor, they will take medical histories, perform diagnostic workups, suture minor wounds, counsel in preventive medicine, and participate in the management of chronic disease. The physician will be freed to focus his skills where they are needed most.

The program at Stanford is supported by grants from the Bureau of Health Manpower of the Department of Health, Education and Welfare, and the California Regional Medical Program.

Stanford's second class, including 20 students, will begin its second year of instruction June 25.

The 16 graduates and their hometowns are listed below:

Marjorie Arendsee, Hayward, CA

Barbara Butler, Hayward, CA

Harold Casaletto, Campbell, CA

William Dennis-Leigh, Mountain View, CA

Larry DePute, Arcata, CA

Charles Despres, Los Altos, CA

Harvey Fine, Marshall, CA

Gary Hamilton, Castro Valley, CA

Don Massie, Redlands, CA

Sergio Noriega, San Leandro, CA

Ronald Pang, Honolulu, Hawaii

Victoria Ramsel, San Carlos, CA

Judith Schrieman, Los Gatos, CA

Robert Scott, Fair Oaks, CA

Ronald Tachibana, Mountain View, CA

Eula Tucker, Arvin, CA

STANFORD--Eleven faculty members were honored at the annual convocation ceremonies of Stanford University School of Medicine Sunday (June 17).

The School awarded medical degrees to 88 men and women. Another 23 degrees were given out, including a bachelor's degree in medical microbiology, 11 master's degrees and 11 doctorates. Diplomas were also presented to 17 graduates in the School of Nursing.

In a departure from tradition, according to the wishes of the graduating medical class, student awards were not presented at commencement. Instead, the 24 students honored, including 18 members of the graduating class, recieved their awards prior to the ceremonies.

The Henry J. Kaiser Award for outstanding and innovative contributions to medical education went to two faculty members: Drs. Oleg Jardetsky, professor of pharmacology and Gerald Reaven, professor of medicine. Dr. Clayton Rich, vice president for medical affairs and dean of the Medical School, made the presentations.

Eight faculty members received the Henry J. Kaiser Award for excellence in teaching, presented by Steven Phillips of the graduating class. They were Drs. Norman Blank, associate professor of radiology; Carlos Camargo, assistant professor of medicine; Halsted Holman, Berthold and Belle N. Guggenhime professor of medicine; Hadley Kirkman, professor of anatomy emeritus; Gerald Levine, assistant professor of pathology; Mark Perlroth, assistant professor of medicine; James Theordore, assistant professor of medicine; and Bruce Tune, assistant professor of pediatrics.

Dr. Paul Wolf, associate professor of pathology, was honored with the Arthur L. Bloomfield Award for excellence in teaching clinical medicine. It was given to him by Ron Rosenfeld on behalf of the graduating class.

Diplomas were awarded by Grace Ringressy, professor and director of the Nursing School and Dean Rich.

Dr. Halsted Holman, an immunologist and a recipient of a Kaiser Award this year, was the keynote speaker for the occasion.

Each of the ten clinical departments have given an award to a graduating student who showed promise in that particular specialty. There were also three awards for outstanding research.

Three book awards named after former Medical School deans were made: The Robert A. Alway Book Award to the medical student who took advantage of unique opportunities available at Stanford; the Windsor J. Cutting Book Award for outstanding performance or promise in pharmacology and the Robert J. Glaser Book Award for outstanding leadership.

-more-

In addition, 12 Alumni Scholar Awards were made to three members in each of the second, third, fourth and fifth year classes, including four graduating students. They are awarded annually by the Stanford Medical Alumni Association primarily on the basis of scholarship.

Most of this year's medical graduates are taking internships in hospitals throughout the United States. Over half have chosen to intern in medicine, but their interests cover a broad range, according to Dr. William Creger, professor of medicine and associate dean of students. "An internship in medicine could lead to one of many medical specialties or to a very general medical practice," he said.

Although only a small number of students chose internships in pediatrics and surgery this year, selections vary with every class, Dr. Creger pointed out, as departmental emphases and teaching models change.

Over the last 25 years, he added, 89 percent of Stanford's Medical School graduates practice medicine, and only a small segment goes into academic medicine or research. He predicted that this year's class would follow at about the same ratio. Award winners and their parents addresses are listed below.

CALIFORNIA

vrence Martin Crapo, son of Philip and Audrey Crapo, 1015 La Vista Road, Santa Barbara; Robert M. Shelton Memorial Alumni Scholar Award and the Medicine Award (Lowell A. Rantz Memorial Award).

James Goodwin Cuthbertson, son of Kenneth and Coline Cuthbertson, 399 Stevick Drive, Atherton; Alumni Scholar Award.

Hans Johannes Dankers, son of Antonius and Jeannette Dankers, 135 Lynn Way, Woodside; Alumni Scholar Award.

Stephen Nimelstein, son of Dr. David Nimelstein, 17342 Mayall St., Northridge; Eli Luke and Jacob David Research Award.

Gaeton Thomas Nola, son of Sebastian and Frances Nola, 311 East Empire St., San Jose; Alumni Scholar Award.

Klaus Porzig, son of Joachim and Anne Porzig, Box 1893, Carmel; Windsor J. Cutting Book Award.

Tom Raffin, son of Bennett and Caroline Raffin, 46 Jordan Ave., San Francisco; Community and Preventive Medicine Award.

COLORADO

Rodney Levine, son of Gerald and Rosemond Levine, 120 South Grape, Denver; Pediatrics Award (Faber Award).

ILLINOIS

Paul Williams, son of Sidney and Ruth Williams, 5445 S. Dorchester, Chicago; Robert J. Glaser Book Award.

IOWA

l Edward Dimsdale, son of Lewis and L.J. Dimsdale, 18 Blackstone, Sioux City; Alumni Scholar Award and Psychiatry Award.

MASSACHUSETTS

Beverly Woo, daughter of Way Dong and Emily Woo, 1 Todd Pond Road, Lincoln; Alumni Scholar Award.

-more-

ICHIGAN

David Edward Avrin, son of Ira and Sylvia Avrin, 18200 Robson, Detroit; Alumni Scholar Award.
Sharon Ann Bogerty, daughter of Walter and Irene Bogerty, 7455 Kipling Ave., Detroit; Alumni Scholar Award and Neurology Award.
Jack Cronenwett, son of Jack and Marie Cronenwett, 807 E. Filer St., Ludington; Surgery Award.
Jeffery Marc Krakower, son of Joseph and Shirley Krakower, 3202 Helber, Flint; Alumni Scholar Award.

MINNESOTA

Geoff Kurland, son of Leonard and Miriam Kurland, 1165 Plummer Circle, Rochester; Gynecology and Obstetrics Award.
Dan Peterson, son of Thorsten and Ruth Peterson, Route 3, Parkers Prairie; General Research Award.

MISSOURI

Peggy Lynn Goldman, daughter of Melvin and Doris Goldman, 8650 Barby Lane, St. Louis; Alumni Scholar Award.

NEW YORK

Richard Anderson, son of David and Lillian Anderson, 1B Bentley Road, Great Neck; Radiology Award.
Jeffrey Arthur Brown, son of Harry and Annette Brown, 73-43 195th St., Flushing; Alumni Scholar Award and Robert H. Alway Book Award.
Ron Rosenfeld, son of Stanley and Deborah Rosenfeld, 591 Astor St., Elmont; Anesthesia Award.

PENNSYLVANIA

bert Bennett Clark, son of Jack and Dorothy Clark, 7964 Bayard St., Philadelphia; Alumni Scholar Award.

WASHINGTON

Gregg Davies, son of Maurice and Constance Davies, 1478 5th St., Chehalis; Eli Luke and Jacob David Research Award.

CANADA

Mary Anne Gail Johnson, daughter of Ina Johnson, 431 East 31st. Ave., Vancouver, B.C.; Dermatology Award.

STANFORD -- A Stanford University Nobel laureate in medicine says that cutbacks in federal training grants to medical schools "was a calamitous decision."

"I could imagine nothing more devastating than to stop training our best young people to do research in basic medical science," said Dr. Arthur Kornberg. "Yet this is precisely what has been done, and the consequences of the decision have not been foreseen."

Kornberg's views appear in the current issue of Science, a scientific journal. He was commenting on the Nixon administration decision earlier this year to phase out medical school training grants worth about $300 million annually.

"For the past five years, the support of science has been visibly ebbing," said Kornberg. "Funds for important research have been cut at a time inflation and advanced technology require increases.

"The support for the training of our best young scientists has been abruptly eliminated. This support for research and training cannot be finely regulated.

"When the flow of science support is turned down, the stream of progress dries up and cannot [illegible]estored for years."

Kornberg stressed the payoffs of the massive support of biomedical science during the past 20 years have exceeded even the most optimistic predictions.

"No one imagined that we would acquire so quickly the firm grasp we have today of the basic designs of cellular chemistry and its regulation," Kornberg said.

In the next 20 years application of chemistry of genes could transform the image of health and disease as dramatically as any advance in the history of medicine, he predicted.

"Nevertheless, those of us who do research in medical science and train young people for such work have witnessed in recent months the most calamitous decision a government of the United States could make for the future of medicine and the welfare of our country," the biochemist said.

The decision cannot be ascribed to economy, Kornberg said. The cost of medical training programs is less than one-half of one percent of the budget for welfare and defense. For weapons research and development alone, $20 billion a year is being spent.

"But now we have been told we can't afford to spend even one percent of this amount to train young people to fight diseases for which crusades have been proclaimed and that we know for certain will kill millions of our citizens each year," Kornberg said.

Noting that in the past 20 years the support of science came from the Congress and citizens t[illegible]fying before committees, Kornberg added:

"The support of science has been and must remain the responsibility of society. It is too important and too complex a problem to be left to scientists."

STANFORD -- Drawings by Dr. Joseph Kriss, a faculty member at the Stanford University School of Medicine, are currently on exhibit at the Los Robles Gallery, 167 Hamilton Avenue in Palo Alto.

The selection of 41 felt tip drawings will be shown through June 14. They were done while Kriss was in Europe and Israel last year. Largely abstract, the drawings include a series of synagogues in Jerusalem, a series of Portofino, Italy and many others of those countries as well as France and Spain.

Kriss, professor of medicine and radiology and head of the division of nuclear medicine, is mostly a self-taught artist. He began painting in 1938, and later took night classes in figure drawing and studied one year with Berkeley artist Jon Cornin.

His works, which include oils and bronze sculptures, range from realistic to abstract. Many of his paintings are in private collections, but two of his largest abstract works are owned and displayed by Syntex Corporation of Palo Alto. Kriss has exhibited several times in the past at Los Robles Galleries.

In addition to painting, Kriss is noted for his research in internal and nuclear medicine, and has pioneered in the development of radioisotope procedures for diagnosing disease. He has been with the School of Medicine since 1948.

STANFORD--A joint pediatric reconstructive surgery program to provide diagnosis and treatment for birth defects was announced Wednesday (June 6) by Children's Hospital at Stanford and the Stanford University School of Medicine.

Announcement of the new program was made by Dr. M. Harry Jennison, executive and medical director of Children's Hospital, and Dr. Robert A. Chase, professor and chairman of the Department of Surgery.

The program represents an effort by the two institutions to provide new patient services to the community and to Northern California. It will be known as the Pediatric Reconstructive Surgery Service and will open at Children's Hospital July 1.

"Specialists from Children's and Stanford will combine efforts to provide comprehensive evaluation of cranio-facial deformities, cleft lip and cleft palate and speech disorders related to palate dysfunction," said Dr. Ernest Kaplan who will head the program.

Kaplan is an assistant professor of surgery in the Division of Plastic and Reconstructive Surgery in the Medical School.

The new program will be coordinated with the activities of the existing Birth Defects Center in the Department of Pediatrics at Stanford Medical Center. Headed by Dr. Luigi Luzzatti, this center is concerned with diagnostic evaluation and treatment of children with birth defects. In addition, the Center is involved in the training of personnel and conducts research in the genetic mechanisms of congenital defects.

"Research carried out at Stanford medical school has made restoration of facial and other bodily features a highly refined art," Dr. Kaplan said. "The program will apply knowledge learned from 10 years of research and clinical evaluations to restore children who a few years ago had little hopes of carrying disfiguring birth deformities and other defects throughout life."

Kaplan said in recent years exciting new techniques for surgical correction of malpositioned facial bones have been developed.

-more-

"As a result, congenital anomalies of the face, clefts of the lip and palate, facial atrophy and other abnormalities can usually be corrected with appropriate reconstructive and plastic surgical measures," he said.

Stanford's surgery department has pioneered in the development of new techniques for diagnosis and treatment of velopharyngeal incompetence or cleft palate speech.

"This congenital disorder can now be treated surgically by a team approach," Dr. Kaplan explained. The patient is evaluated by pediatricians, neurologists, speech pathologists, dentists and plastic surgeons. In addition, he is tested for hearing deficits and has special x-ray motion pictures taken.

This is a continuous film recording (cinê-voice study) of the patient speaking during a fluorocopic examination. The technique allows doctors to visualize the movement of the soft palate while the patient is speaking or swallowing. The technique has been one of the most important in diagnosing cleft palate speech and prescribing treatment.

One of the problems in treating clefts of the lip and palate and associated speech disorders is the coordination of team efforts, said Kaplan.

To improve teamwork, the Pediatric Reconstructive Surgery Service will computerize clinical information for each patient seen at Children's Hospital so that data can be easily retrieved by physicians or parents who need medical information. This databank will also serve as a precise source for evaluation and further improvement in patient care.

"The additional bonus of centralizing this information," Kaplan said, "is the increase in medical knowledge to be gained by having accurate and complete records that can be rapidly processed by the computer."

In 1968, the Children's Hospital at Stanford, a separate corporate entity located on Stanford lands, and the School of Medicine agreed to develop joint programs for the purpose of reducing unnecessary and costly duplication of facilities and staff, assisting each other in attaining comprehensive medical care for children, and providing the best possible opportunities for pediatric teaching and research.

Other clinical programs located at Children's include the nationally recognized pediatric cancer and hemophilia care programs, a new orthopedic service, and programs in allergy, rheumatology, chronic lung diseases, and physical medicine and rehabilitation.

Another Stanford program located at Children's is the Center for Communications Disorders.

The two institutions are also developing common systems of medical records, and share radiotherapy and surgical facilities as well as highly specialized laboratory services.

STANFORD--Dr. Wilbur B. Hurlbut of New York City is the new president of the Stanford Medical Alumni Association, and Dr. Robert E. Berner of Palo Alto is the new president-elect.

Dr. Hurlbut assumed his duties at the conclusion of the Spring Reunion of the Association on the Stanford campus. He will serve as president through July 1974, succeeding Dr. Theodore W. Loring of Eureka, Calif.

Dr. Hurlbut is an attending physician and chief of dermatology at the Roosevelt Hospital in New York City. He is a member of the New York Supreme Court malpractice arbitration panel. He has served on several committees and panels of the New Academy of Medicine including the executive committee on public health, the section on dermatology, and the admissions committee. He is also former president of the Manhattan and Metropolitan Dermatology Societies, and a member of the Stanford Medical School visiting committee.

Dr. Berner is a plastic and surgical consultant and a member of the clinical faculty of the Stanford University School of Medicine. He has served in that capacity for the past 23 years, and has also been active in the alumni association as a member of the board of governors.

STANFORD — In an apparently unprecedented action, two investigators from the Santa Clara County District Attorney's Office, using a search warrant to gain entry, attempted to search the medical record files of the Stanford University psychiatric clinic, Friday, June 1, seeking evidence that might assist them in the prosecution of an alleged sex offense case.

The warrant, signed by Judge Paul R. Teihl in San Jose Municipal Court, was for the records and documents relating to the victim in the case, a 19-year-old youth who was examined after the alleged attack last February.

Cassius L. Kirk, University legal counsel, said there was no question about the validity of the request for records, since the patient had signed a document waiving the confidentiality of his medical record.

But Kirk said he was surprised that a search warrant was issued when a court order after a hearing involving both parties would have done the job.

Two investigators from the district attorney's office, Anthony Cvetan and Duane Sands, showed up at the psychiatric clinic building about 10 a.m. Friday with the search warrant.

Peter Carpenter, assistant vice-president for medical affairs, met them and surrendered the file on the youth while telling the investigators that they could not go through the psychiatric files because of the confidentiality of the names of other patients.

The investigators complied and did not conduct a full search.

The psychiatrist who examined the patient and saw him several times since is Dr. Marguerite Lederberg, a psychiatric resident at the School of Medicine. She was not present when the investigators appeared at the clinic.

The warrant authorized an immediate search of offices, file rooms, storage areas, closets, and a library in the clinic, as well as Dr. Lederberg's car and residence at 1431 Pitman Avenue, Palo Alto. She is the wife of Nobelist Dr. Joshua Lederberg.

It listed as objects for the search the file or files on the youth and any other "records, papers, documents, or notes" relating to the patient's case.

Dr. Lederberg and her attorney, Jerry Marer, appeared Friday afternoon before Judge John Brenner in Santa Clara County Superior Court in an attempt to get him to stay the order on the additional documents listed in the warrant or to seal the files until the psychiatrist could discuss the case with the judge.

Dr. Lederberg said she was advised by her attorney not to comment on the case.

STANFORD -- A Stanford University psychiatrist Friday (July 27) said statements made in a newspaper story about President Richard M. Nixon's state of mind are "foolish and demeaning."

Dr. C. Peter Rosenbaum, associate professor of psychiatry, issued a response to a story which appeared in today's edition of the Stanford Daily, a student newspaper, and was attributed to the Chicago Sun-Times.

However, when contacted to verify the report, a spokesman for the Chicago paper denied that such a story had appeared in this morning's edition or wire service. The Stanford Daily editor could not be reached for comment.

According to the Stanford Daily, Stanford psychiatry classes have used a tape of President Nixon's concession speech in the 1962 gubernatorial election in which the President said, "You won't have Nixon to kick around anymore, because gentlemen, this is my last press conference."

The Daily said that according to the Chicago Sun-Times story, this tape was used to demonstrate a classic example of "acute paranoid state."

In his response, Rosenbaum said he used an audio tape of the speech in teaching a seminar for the psychiatric staff "because I wanted to demonstrate the different ways in which people can respond to stress, and also how they can recover in a supportive environment."

Nixon, he went on, reacted very temporarily to stress in a way it could have occurred in virtually everybody.

"It would be foolish and demeaning to draw any further inferences about his character or make-up on any more profound level," Rosenbaum said.

The psychiatrist said that Nixon's 1962 address received wide coverage, and no one who heard it or saw it was likely to forget it.

"Mr. Nixon's reaction was clear and vivid. It was used for teaching purposes along with many other examples showing the virtually universal effects of stressful experience," Rosenbaum said.

The last time the tape was used for teaching was in 1966.

Speaking of the 1962 campaign, Rosenbaum said it had been rough and exhaustive. "The stress on the candidates had been incredible. Physical stress and exhaustion showed themselves in many ways. In Mr. Nixon's case it was the statement that he made.

"Such an angry response to stress is no respector of party, person or occupation," the psychiatrist said. "It has happened to Democrats and Republicans, to doctors, to businessmen, and to soldiers in ombat."

He added most persons who have a significant reaction to the various types of stress never see a doctor or a psychiatrist, but instead recover with the support of their families and friends.

STANFORD -- Nurses and technicians who work with kidney dialysis patients require a unique combination of skills. For, in addition to their medical and technical responsibilities, they must be able to meet the many psychological needs of patients who are forced to depend on an artificial kidney machine for life.

"Helping patients live with dialysis and the restrictions it places on their lifestyle is a large part of our work," says Pam Simmons, head nurse in the Renal Care Unit (RCU) at Stanford University Hospital.

Chief technician Martin Hudson put it another way: "In between operating the machines and instructing patients, we play father confessor, provide emotional support, and try to give patients some incentive to learn as much as they possibly can."

Technicians in Stanford's RCU receive six months of intensive on-the-job training, including basic kidney physiology and equipment mechanics. Their primary responsibilities are the operation, maintenance, and repair of the dialysis machines.

Nurses complete one month of formal training, "but it usually takes six months before they are fully oriented to the unit," Miss Simmons says. When the patient is on dialysis, nurses "take care of his physical well-being and monitor blood pressure and blood volume, as well as helping him cope," she says.

Stanford has five beds for chronic dialysis patients who need the treatment two or three times weekly, one bed for acutely ill patients, and one for home training sessions. In all, the 18 nurses and 7 technicians conduct about 400 dialysis runs per month.

Patients on chronic dialysis are encouraged to assume responsibility for much of their own care, Miss Simmons says. This includes care of the shunt which connects the patient to the machine, monitoring the operation of the machine, and resetting alarms.

In home training, the educational process is much more intense, as the patient and his assistant are taught to become more and more self reliant.

The program, conducted by one nurse and one technician, includes four sessions per week for six to eight weeks. Three times each week, while on dialysis, the patient learns "how his body acts and reacts to the machine," Miss Simmons says. The fourth session is totally machine-oriented.

Hudson breaks the technical instruction down into five main areas: "the theory of how the machine does its job; preparing the machine for a dialysis run; controlling it during a run, recognizing [illegible]er signals and how to respond to them; maintaining the machine--how to keep it safe and clean; and finally, ordering of supplies."

-more-

Throughout the program, the patient and his assistant receive continual verbal and written testing, including problem-solving and reacting to hypothetical situations that may arise.

"Additionally, the nurse and technician meet constantly to discuss progress, problems, and new teaching methods that might be used," Hudson says. "It's up to us to be observant of the patient's physical and mental well-being. The doctor is always available for consultation and plays an active role in the care and support of the patient."

Though nurses and technicians now assume much of the responsibility for management of the dialysis patient, this wasn't always the case.

"In the early days of dialysis, the only thing the nurse did was bring coffee and donuts to the doctor who was running the patient," Miss Simmons laughs.

For many years, dialysis involved surgical cutdowns on a major blood vessel each time the treatment was needed, since no permanent access to the bloodstream had been developed.

"This made it impossible to dialyze a patient over a long period of time," says Dr. Norman Coplon, director of Stanford's RCU. "With the repeated surgery on the major vessels, doctors soon ran of places to tap into the patient's bloodstream."

In 1960, development of the arteriovenous shunt ushered in a new era for dialysis. Silastic tubes implanted in the patient's artery and vein (connected together when not in use) provided the necessary open access to the bloodstream.

Since then, Coplon says, many other advances have been made.

"Dialysis machines have become more compact, more efficient, and easier to operate," he says. "Additionally, doctors have developed the use of the fistula, whereby a patient's artery and vein are connected internally. Using this access, there is less chance of clotting or infection."

For the patients who must rely on dialysis, whether it be for lifelong treatment or to carry them along until a transplant is possible, these advances can mean safer treatment and a more normal life.

STANFORD -- For many people, serious illness comes suddenly, without warning. Virtually overnight, family life is disrupted, savings are wiped out, and future plans are forgotten.

When the problem is kidney failure, the emotional and financial repercussions are even more profound. The only treatment options are lifelong dialysis on an artificial kidney machine, or a transplant. Both are unpleasant, demoralizing, and extremely expensive.

Some 10,000 Americans currently are being kept alive by dialysis machines which take over the kidney's main task of filtering out impurities from the bloodstream.

But dependence upon a machine for survival can cause depression in many patients, says Lois Christopherson, chief social worker in the Department of Surgery at Stanford University Medical Center.

"If you're not a candidate for a transplant, the worst aspect of dialysis is that it's a lifelong proposition," she says. "You have to face the prospect of spending six to 12 hours a day on dialysis, two or three times a week, for the rest of your life."

With one family member virtually tied to a machine, the pressures on family life are considerable.

"Frequently, patients have serious guilt feelings at putting such a strain on their families," Miss Christopherson says. "Suddenly it becomes impossible to plan for the future or take trips to places that do not have dialysis centers.

"There are also sexual problems. Many patients become impotent or have a decrease in sexual drive."

If their job does not involve physical labor, dialysis patients can usually maintain employment. However, most are unable to change jobs because they cannot pass required physical examinations, Miss Christopherson says. Additionally, many companies are reluctant to take a chance in insuring a dialysis patient.

Medical complications pose a constant threat. The shunt which connects the patient's arm or leg to the dialysis machine can become clotted, and infections around the shunt area are common.

Despite the difficulties associated with dialysis, some patients prefer it to a transplant.

"To these patients, a transplant represents the unknown," Miss Christopherson says. "It's a new risk, involving major surgery and the ever-present threat of rejection.

"Dialysis, for all its problems, is a known, understandable, and predominantly successful way to keep the patient going."

With the growing sophistication of artificial kidney machines in the past five years, death rates for dialysis patients have dropped to 10 to 15 percent the first year, and under 10 percent for each year thereafter, says Dr. Norman Coplon, director of the Renal Care Unit at Stanford University Hospital.

At the same time, advances have been made in transplantation. Since the first kidney transplant 20 years ago, more than 13,000 have been performed. In the last five years, survival statistics have risen to 85 percent for one year with a related donor and 70 percent with a cadaver donor.

-more-

Increasingly, kidney patients are electing to undergo a transplant, utilizing dialysis as a stopgap measure until a donor is available.

But once a patient decides on a transplant, he and his family must face the awkward and guilt-ridden question, "Who will be the donor?"

"The problem is, how do you ask someone in your family to give you a kidney?" Miss Christopherson says, "If family members line up and offer, that's one thing. But if the patient has to ask, he feels embarrassed and even more responsible for the donor's life than he would otherwise."

On top of all the psychological and medical problems posed by kidney dialysis and transplantation, the costs are tremendous.

Most kidney transplants cost between $15,000 and $20,000, but expenses can be as low as $10,000 when things go smoothly and as high as $40,000 when there are serious complications.

A dialysis run at most centers costs approximately $200. Considering that most patients require three treatments per week, "it costs roughly $30,000 a year to stay alive on dialysis," says Pam Simmons, head nurse in Stanford's Renal Care Unit.

The financial picture brightened considerably for kidney patients July 1, when federal legislation went into effect which covers most expenses for dialysis and transplantation.

The bill, H.R. 1, is an amendment to the Social Security Act. It is expected to cover an estimated 90 percent of the population, says Bill Stein, executive director of the Kidney Foundation of Northern California.

"The government will pick up 80 percent of approved costs from the third month of dialysis through one year post-transplant," Stein says. "If the transplant fails, the patient can re-establish his eligibility in an artificial kidney program."

In addition to pulling patients out of a financial hole, H.R. 1 may have another positive effect--triggering the development of more dialysis and transplant centers all over the country.

Currently, because of a shortage of adequate facilities, many terminal patients are unable to get the treatment they need. Kidney disease now kills some 60,000 Americans annually and is the fourth leading cause of death in this country.

California has 66 artificial kidney centers and 16 transplant centers, according to the Kidney Information Bureau at the State Public Health Department. But only New York has comparable facilities.

"There's no question that, in various states, a lot of people are dying who could be saved with the proper treatment," Dr. Coplon says.

"Up to now, many parts of the country have been reluctant to get into kidney dialysis and transplantation because of the high cost and the inability of many patients to pay. But with H.R. 1, there should be a big upsurge in these services all over the country."

Editors: First in a three-part series.
Photos available on request if not included with release.

STANFORD -- Like most people, Dee Eads never gave much thought to her kidneys. She'd never had a major illness and was "just going along great."

But her life changed dramatically in August of 1970, when she was stricken with a serious kidney disease and nearly died. For two and a half years afterward, aided by heavy doses of medication, she "limped along" on two failing kidneys. Then, in March of this year, her kidneys gave out altogether.

Today, the attractive 38-year-old housewife is one of nearly 2,000 Californians who are kept alive by an artificial kidney machine.

The machine takes over the job her diseased kidneys cannot perform, filtering out poisons and waste products from her bloodstream. Without this process, known as dialysis, she would soon be poisoned by the impurities in her system.

Two small plastic tubes implanted in an artery and vein in Dee's arm provide the link between her bloodstream and the dialysis machine. Her blood is carried from the artery to the machine, where it is cleansed, and then back into the vein.

This tiresome filtering process, which must be repeated three times per week, takes Dee five hours to complete, since she is only 4'11" tall. (It can require up to 10 hours for patients who are larger or who have medical complications.) Another two hours are spent preparing the machine beforehand and washing it at the conclusion of dialysis.

For many patients, unable or unwilling to have a transplant, dialysis represents a way of life. For others, like Dee, it is only a temporary measure to carry them along until a donor kidney is available.

"I'd definitely like to get a transplant," Dee says. "I don't want to live the rest of my life attached to this machine. I'd rather have a transplant and take my chances."

Worldwide, over 12,000 patients have taken their chances on a kidney transplant. Some 5,500 are now living with a functioning kidney; another 2,000 have returned to dialysis after unsuccessful transplants.

A patient who receives a kidney transplant from a related donor now has an 85 percent chance to survive one year; when the kidney comes from a cadaver donor, the one year survival rate is 70 percent. For two and three years, the statistics are nearly as good.

In Dee's case, the kidney will have to be from a cadaver donor. Her two children, aged 16 and 10, are too young to be donors, and her father is too old. She also has a brother, a missionary in the Philippines, but the blood types do not match.

"I think I'd really rather have a cadaver donor than involve someone else," Dee says.

Her name was recently added to the list of patients awaiting transplants at Stanford University Medical Center.

"Now it could be two weeks or five years before someone dies who cross-matches well with me," she says.

-more-

Until then, she must depend on the dialysis machine. But unlike most patients, who must travel to a medical center three times a week for treatment, Dee can perform dialysis in her home in Danville (a suburb of Oakland).

Last month, she and her husband, Hal, completed an intensive six-week home training program at Stanford Hospital. The course includes basic kidney physiology, as well as the operation, monitoring, and maintenance of the machine.

At the conclusion of the program, the Eads took home the dialysis machine they used during their training. It was donated by the Kidney Foundation of Northern California, saving them an expenditure of some $6,000.

In recent weeks, a plumber has been out to the house to install a sink and drainage system in the family room, where Dee goes on dialysis three times per week. Hal has also constructed a medical pantry to store the various supplies that are needed.

The training program cost the Eads nearly $4,000. But most of their maintenance costs ($10,000 the first year and $3,000 to $5,000 each year thereafter) will be assumed by the federal government through new legislation which went into effect July 1. Under the new bill, H.R. 1, the government is expected to pay about 80 percent of the costs of dialysis or transplantation for most Americans.

Prior to the passage of H.R. 1, many dialysis patients were forced to use their life savings, borrow large sums of money, or go on Medi-Cal to cover their medical bills. This was particularly true of patients undergoing long-term dialysis at an artificial kidney center, whose yearly bills can reach $30,000.

Perhaps more so than the financial effects, Dee has been concerned over the strain her illness has put on her family.

"It may seem crazy," she says, "but I feel guilty about this whole thing. If you can be sick and involve just yourself, that's one thing. But to inconvenience everyone else, you can't help but feel really guilty.

"Right now my experience is the biggest thing in our family. It's been hanging like a cloud over us for a long time."

The inconvenience, the expense, and the basic unpleasantness of dialysis, as well as the ego-destructive nature of having to depend upon a machine for life, causes extreme depression in many patients. Dee looks at it differently.

"It's really not that depressing," she says. "I'm just glad to be alive and have the time."

Although her future is still somewhat uncertain, she has definite feelings about it.

"It's hard to convince people that I have a sense of urgency about things I want to do," she says. "Lots of people think they'll live forever. I know I won't, so I want to enjoy my family and do the things that are meaningful to me. I don't want to waste my time on unimportant things."

For now, what's important to her is being a good wife and mother. "It's a hard job," she laughs. "I've never found it dull for one second."

STANFORD -- An overall 4.65 percent increase in prices beginning Saturday, July 21, was announced today (July 19) by Stanford University Hospital.

The bulk of the increase will be reflected in daily room rates, but virtually all other charges will remain unchanged, said Dr. Thomas A. Gonda, hospital director.

For community patients, the daily room rates will now be $78.00 for medical and surgical wards. Semi-private rooms will be $85.00 and private rooms $95.50. Obstetrical ward rooms will now be $79.50, with nursery rooms $56.00.

This represents an increase of $9 to $11 for daily rates.

Dr. Gonda said the increase is necessary "to meet the continuing rise in operating costs, including employee wages and materials. But nearly all other prices which make up a patient's total hospital bill, such as drug charges and most laboratory tests, will remain unchanged," he said.

Last year Stanford raised room rates $4.50 to $5.00; the year before, there was an increase of about $4.00. However, these increases were accompanied by proportional increases in laboratory, drug, operating room, and similar charges, Dr. Gonda said.

This year's overall increase of 4.65 percent is in compliance with Phase Four guidelines, the hospital director said.

ADVANCE FOR P.M. RELEASE JULY 19, 1973

STANFORD — Scientists at Stanford University Hospital have found that some patients undergoing long-term treatment on artificial kidney machines develop deficiencies in an important body enzyme which may be caused by the "washout" of a vitamin.

To correct this deficiency and avoid possible harmful effects, supplemental doses of the vitamin (known as B_6 or pyridoxine) should be given to these patients, the researchers said.

Currently, some 2,000 Californians and 10,000 Americans are kept alive by machines which take over the kidney's main task of filtering out poisons and waste products from the bloodstream. Without this process, known as dialysis, they would soon be poisoned by the impurities in their systems.

Eleven of 19 patients recently undergoing chronic dialysis at Stanford Hospital were found to have markedly decreased levels or a total absence of the enzyme, aspartate transaminase (GOT). GOT plays a vital role in body metabolism.

The researchers—Drs. Paul L. Wolf, Norman Coplon and Alan S. Coulson, and medical technologist Dorothy Williams—reported their findings today at the annual meeting of the American Association of Clinical Chemists in New York.

"A possible explanation for the low or absent GOT activity is a washout of the enzyme itself," Wolf said in an interview. "But we believe it is the vitamin, pyridoxine, which is being washed out in dialysis."

The pathologist explained that pyridoxine acts as a "co-enzyme" and is needed for GOT to function. It is also essential for body growth and is actively involved in red blood cell production, as well as the functioning of the body's nervous and immune systems.

"Up to this point, the only known common condition which causes low GOT activity is pregnancy," Wolf added. "Here again, this may relate to a deficiency of vitamin B_6 which occurs during pregnancy." (None of the 19 patients in the study was pregnant.)

Scientists have previously determined that vitamin C and folic acid are both washed out by long-term dialysis. To avoid possible harmful consequences such as anemia and impairment of the blood's clotting mechanism, doctors now prescribe supplemental doses of both vitamin C and folic acid for dialysis patients.

Similarly, the Stanford researchers believe, doses of pyridoxine should be administered to dialysis patients.

"It is important to maintain GOT activity, and to have pyridoxine in the blood," Wolf said. "Without it, patients can develop a wide range of problems, including neurological disturbances, anemia, kidney stones, dermatitis, and depressive disorders associated with oral contraception."

In an upcoming study, Wolf and his associates will specifically measure pyridoxine levels in dialysis patients at Stanford.

STANFORD -- Last October, doctors in Western Samoa removed an eye with a cancerous tumor from three-year-old Iona Sakalia and told his family there was no hope for the boy.

Today, the Samoan youngster is one of the most active patients of the Children's Hospital at Stanford, where he has responded extremely well to treatment, according to physicians.

Iona, who will be four in August, came to Stanford in January with his father. "He was a very ill child, with a tumor the size of a grapefruit growing from his right eye socket", said Dr. Jordan Wilbur, head of the Pediatric Oncology Unit at Children's Hospital.

The condition, called retinoblastoma because the tumor starts in the retina of the eye, occurs in young children. When it is treated in the early stages by radiation therapy or surgery, the survival rate is excellent, noted Wilbur. With Iona, however, the tumor was infected, and the cancer had spread to other areas.

"Perhaps by other standards, Iona's case would have been considered fatal," said Wilbur, who acknowledged the tumor was one of the largest he had seen of its type. "But we always feel that we can try a therapy that has not failed in the past for similar, though less severe cases."

After intensive treatment that included antibiotics to combat infection and powerful drugs and radiation to shrink the tumor, "all evidence of tumor has been brought under control," Wilbur reported.

The entire cost of care and treatment for Iona is being underwritten by Children's Hospital. Transportation for both the child and his father to California was covered by the San Francisco Eye Institute medical group.

Currently, Iona has the distinction of being the patient with the longest stay in the oncology unit. Wilbur expects the child will be ready to leave the Hospital in a couple of weeks, but said he will have to remain nearby for some time.

During their stay here, father and son have grown remarkably close. They share a room at the Hospital and spend much of their time together. Iona has been able to take a few short trips with his dad, including one to Los Angeles to visit an uncle and see Disneyland.

"It's been a gradual upward trend for Iona," said Mary Nehring, social worker on the oncology service. "He has really blossomed." She also said that his father, Sakalia Peniata (in Samoa, the father's first name becomes the child's last name) has adapted remarkably well.

Peniata left his wife and three children to come to a strange country with a sick little boy. Now he is familiar with the Bay Area and at ease with the English language, which he said he hadn't used much since school.

It all began, recalled Peniata, about one and a half years ago, when he and his wife noticed a white speck on the pupil of Iona's right eye. Then, last summer, the eyeball started to bulge, and the tissue was found to be malignant.

-more-

The eye was removed in October by the only ophthalmologist in Western Samoa, but the tumor continued [illegible]row. By December, Iona was so weak he could not walk or talk. "I carried him in my arms day and night," said his father. "Hospital officials told me to go home, because there was nothing more they could do."

Shortly before Christmas, though, the eye surgical team of the San Francisco Eye and Ear Hospital went to Western Samoa to perform surgery. Dr. John Beale, Jr., an ophthalmologist on the team, examined Iona and told Peniata he would try to arrange for treatment in the United States.

When he returned to San Francisco, Beale contacted Children's Hospital and made arrangements for Iona to be treated in the oncology unit. The Eye Institute medical group, which Beale heads, sent Peniata plane tickets for the trip. When the father and son arrived in San Francisco, January 10, Beale and his wife drove them to Children's Hospital.

Wilbur noted that it was unusual to see a tumor as large as Iona's because in this country, it would have been treated earlier. He also said that when the disease has invaded other parts of the body, it is usually fatal.

Iona had evidence of cancer in his central nervous system, blood, bone marrow and liver, among other places. He was started on a very intensive therapy program based on the philosophy of the oncology unit which Wilbur summed up:

"In patients who have no chance by anyone's standards, we should be willing to take risks, as long as the side effects from chemotherapy and radiation are no worse than the tumor itself. And the tumor was destroying Iona."

Wilbur explained that Iona was administered antibiotics to fight the infection and build up his resistance. [illegible]he same time, an aggressive chemotherapy program was begun, using powerful drugs to shrink the tumor [illegible]rid Iona's system of proliferating cancer cells. After the tumor had decreased in size, he received radiation therapy to eradicate any residual disease.

"Now Iona couldn't be doing better," said Wilbur. He will continue to receive intensive treatment for the next year or two, and eventually may be a candidate for plastic surgery to correct the bulge under his right eye that the tumor caused.

"With all the excellent care and love he has been given, Iona has become quite spoiled," said Peniata after he affectionately reprimanded his son for making too much noise. "But it's worth it," he added, just to see him laugh and run again."

Peniata admitted he never expected such a recovery. "It took eight bandages to cover the tumor when we arrived, and now there are none; that's progress," he pointed out jubilantly.

Although he cannot work in this country because of immigration laws, Peniata has managed to keep busy. A skilled carpenter and welder by trade, he has done volunteer work welding wheel chairs for the Hospital and repairing playground equipment for a church in Menlo Park. He also enjoys swimming with the children in the pool or at the Hospital, and entertaining on his guitar.

Meanwhile, Iona is happily running around the Hospital, babbling away in a strange mixture of Samoan, English and baby talk.

Children's Hospital at Stanford is a separate corporate entity located on Stanford lands and affiliated with the Stanford University School of Medicine. The cancer program is part of an effort by the two institutions to strengthen patient care, teaching and research in problems of malignant diseases in children.

Other clinical activities now located at Children's Hospital include a joint pediatric reconstructive surgery program, an orthopedic service, hemophilia care, and programs in allergy, chronic lung diseases, [illegible]umatology, and physical medicine and rehabilitation.

The Medical School and Children's Hospital also share radiotherapy and surgical facilities, as well as highly specialized laboratory services.

STANFORD -- Dr. Albert J. Stunkard, a nationally known expert in human eating disorders, has been appointed professor and chairman of the Department of Psychiatry at Stanford University School of Medicine.

Dr. Stunkard has been professor and head of the Department of Psychiatry at the University of Pennsylvania School of Medicine since 1962.

His appointment, announced today (July 9) by Dean Clayton Rich, becomes effective September 1. He succeeds Dr. Bert Kopell, who has served in an acting capacity since Dr. David Hamburg resigned last August.

Dr. Stunkard, 51, has carried out wide ranging research into the psychosomatics and treatment of human eating disorders, including both obesity and pathological under-eating.

He identified and offered clinical descriptions of the "night eating syndrome," a pattern of food intake which characterizes patients who are particularly resistant to weight reduction regimens.

He published the early observations of "dieting depression," a psychological response seen in some individuals who attempt to lose weight. With two associates, he also published findings on the close and systematic link between incidence of overweight and social class in an urban American population.

Dr. Stunkard is the author of 85 publications, including the chapters on obesity and under-eating in most standard textbooks and reference works. His new book, Understanding Obesity: The Biography of an Endeavor, is currently in press.

A native of New York City, he obtained his B.S. from Yale University in 1943 and his M.D. from Columbia University in 1945. He served his internship at Massachusetts General Hospital and his psychiatric residency at Johns Hopkins Hospital.

After postdoctoral research fellowships at Johns Hopkins, Columbia, and Cornell University, he was appointed instructor in medicine at Cornell in 1954.

Dr. Stunkard joined the faculty at Pennsylvania in 1957 as associate professor of psychiatry. He was promoted to professor and appointed department chairman five years later. In 1968, he was named Kenneth Appel Professor of Psychiatry.

A member of the major professional and academic societies, he is president-elect of the American Psychosomatic Society and past vice president of the Association for Research in Nervous and Mental Diseases.

In 1960, he won the Hofheimer Prize, the annual award of the American Psychiatric Association for outstanding research.

Dr. Stunkard has served on numerous national research committees and panels focusing on psychiatry, behavioral sciences, and food and nutrition. He is currently on the editorial boards of three professional journals.

STANFORD -- Many people who complain of insomnia may actually be suffering from sleep apnea, the temporary cessation of breathing during sleep, researchers at Stanford University School of Medicine have discovered.

This finding means that rather than large doses of sleeping pills, an evaluation of respiratory functions during sleep may be required for some patients with insomnia, the researchers said.

Six insomniacs undergoing treatment at the Stanford Sleep Disorders Clinic were found to be suffering from sleep apnea, according to Drs. Christian Guilleminault, William C. Dement, and Frederic L. Eldridge. They reported their findings with the first two patients in the current issue of Science, a scientific journal.

Both patients experienced severe sleep disturbances caused by repeated episodes of apnea, in which breathing stopped for periods of 20 to 150 seconds. These episodes were followed by arousal, often complete awakening, and resumption of breathing. Arousals numbered as high as 250 per night.

"It was clear that the sleep disturbance was directly associated with the apneas," the authors wrote. "It is almost certain that there is a functional association between the sleep disturbance giving rise to the complaint and the apnea."

The researchers raised the possibility that insomnia with sleep apnea may induce cardiovascular problems. In one patient, a substantial increase in blood pressure in the pulmonary artery during sleep was noted.

"The question of the possible interaction of sleep apnea and insomnia with cardiovascular disease should at least be considered," they wrote. "Can we speculate that night-time death in some such patients could be related to sleep apnea? This possibility should also be considered."

Research along these lines is now proceeding at Stanford.

In an interview, Drs. Guilleminault and Dement said that as many as 10 percent of all insomniacs may actually be suffering from sleep apnea.

"Of chronic insomniacs seen at the Sleep Disorders Clinic, 10 percent have had sleep apnea," Guilleminault said.

-more-

Estimates of insomniacs in this country have ranged as high as 20 million, but no reliable, comprehensive survey is available, Dement said.

The rare condition of sleep apnea was first described in 1965 in obese patients ("Pickwickian Syndrome"). Three years later, it was reported in patients with hypersomnia or excessive sleeping tendencies.

The two patients described in Science, who were first seen in 1972, represent the first cases of sleep apnea associated with insomnia.

Both patients had "central" apnea, involving a stopped diaphragm apparently related to a hidden nervous system defect. The mean duration of their apneic periods was 30 seconds, with a range of 20 to 150. Repetitive apneas often lasted 20 to 30 minutes, and one patient spent 42 percent of his sleep time in apnea during a three-night test period.

"In these patients, the simultaneous resumption of breathing occurs when oxygen in the blood gets so low and carbon dioxide so high that the brain sends out an emergency signal that it needs oxygen," Guilleminault said.

He also noted that all six clinic patients suffering from sleep apnea claimed that their condition worsened after they took sleeping pills, particularly barbiturates.

STANFORD -- Young people in Palo Alto can receive free medical care at a health clinic in the North County building on Grant Street.

Called Our Health Center, it is staffed by physicians, nurses, laboratory technicians and others from Stanford University Medical Center and the community, who volunteer their services.

The clinic, with the cooperation of the Santa Clara County Health Department, has been operating for over a year. Although the county provides space in its North County building and furnishes some supplies, the clinic relies largely on outside donations and volunteers.

When the clinic is open, there is always a full house. However, more physicians and other staff are needed, says Dr. M. Harry Jennison, chairman of the Midpeninsula Urban Coalition's Health Task Force, which is interested in helping the clinic. Jennison, director of Children's Hospital at Stanford, explains that a doctor must be on the premises for the clinic to treat patients, because by law, only an M.D. can make a diagnosis or prescribe drugs.

The ideal shift for volunteers is two to three hours once a month, but that schedule requires a larger pool of personnel, according to Christine Palmer-Persen, clinic director. "We really need physicians," she notes, "because they are usually too busy to give more than a few hours a month. Yet now, some work every week."

The walk-in clinic, open Mondays and Thursdays from 3 to 8 p.m., has between 20 and 40 patients an evening. "It is diagnostic," explains Jennison, "and not intended to be a full-fledged primary care facility. More serious problems are referred to Stanford or elsewhere."

Modeled after other free health clinics in the state, Our Health Center is the only clinic in the area that treats transients, says Miss Palmer-Persen. Patients are mostly 17 to 24 years old, many of them sons and daughters of middle class parents. They are medically indigent because they are not living at home or are ineligible for other health plans," she says.

Their health problems range from veneral disease to strep throat or poison oak. About 40 percent come in for gonorrhea and another 20 percent for an unplanned pregnancy, continues Miss Palmer-Persen. She emphasizes, however, that the clinic is concerned with furnishing good care for any medical problem.

-more-

Trained medical assistants and counselors take histories, aid the physician and/or nurse with the examination, advise patients in dealing with their problems and help with any referrals or follow-up. Basic laboratory tests are performed by licensed medical technologists and assistants at the clinic.

Jennison believes the clinic provides a valuable service for the Midpeninsula. "Thanks to the clinic, a certain part of the population is being reached for a modicum of health care when normally it wouldn't have any through traditional medical channels," he said.

He thinks the experience at the clinic can benefit medical students, house staff and others interested in medicine. "But above all," he points out, "it's really a labor of love."

Most of the Stanford volunteers claim that the desire to do something worthwhile in the community, as well as the personal enjoyment and value of the experience, prompts them to give their time to the clinic.

Dr. William Watson finds the clinic interesting because he sees different kinds of medical problems than he does as attending physician and clinical assistant professor of dermatology at Stanford. Yet, he acknowledges it can be frustrating.

"It is sometimes difficult to communicate with the patients because they have different lifestyles and values, but it's challenging and interesting." Watson adds that he also enjoys being among the young people who run the clinic because they are so enthusiastic.

Both he and Dr. Stanley Derezinski, a Stanford fellow in infectious diseases, feel the clinic offers good experience in primary care. "Having outpatient contact and dealing with routine medical problems is helpful, especially for those trained in a university hospital," says Derezinski. He finds the problems more similar to those he saw in the Army than he did while training as a resident in internal medicine.

There is a need for specialists, particularly gynecologists, say the physicians. The clinic is trying to set up a referral system of community physicians for problems the clinic can't handle. A backup system would also help the physicians on duty who may want to consult with doctors in other specialties.

Laboratory work is essential to diagnose many conditions, and the quicker tests are completed, the sooner treatment can begin. Coordinator of the lab is Terry Fotre, assistant in the Hospital's Clinical Laboratory. Volunteer medical technologists and trained assistants do complete blood counts, urinalyses, microscopic smears and bacteria cultures at the clinic. More elaborate tests are contracted to other labs for little or no cost.

"About two-thirds of the patients seen require several tests," says Fotre, "so on a busy night the lab does some 60 to 80 tests." Fotre, who wanted first-hand experience before applying to medical schools, feels the clinic has been invaluable for him. He also points out that some medical technologists consider it a way to review the more routine tests they may not do if they have specialized.

For other young people like Fotre, the clinic is a place to obtain practical experience. Betsy Allyn, a technician in the Department of Dermatology who starts medical school in Utah this fall, wanted prior contact with patients. She enjoys being a medical assistant or counselor, but also helps with lab work when necessary.

-more-

Assisting and counseling are interchangeable, she explains, depending on what is needed. "Ideally the same person should follow a patient, from the interview and medical history through whatever counseling or follow-up care is required, but we don't have the personnel for that."

Dermatology research assistant John Walsh, planning on a career in biochemistry, thinks what he is learning about different diseases at the clinic may influence his research later. He has also been helping with publicity by taking photographs for posters.

When Adele Daly, director of Central Service, decided to do some volunteer work as a nurse, she had mixed feelings about the lifestyle of some of the patients, but felt the clinic was a worthy undertaking.

"Health care should be available to as many people as possible, including young people alienated from their families," she says. "The fact that the clinic exists, encourages people to seek help."

Mrs. Daly admits she occasionally feels a "generation gap," but says the casual atmosphere of the clinic helps overcome it. No one wears a uniform, and many of the staff with their long hair and faded blue jeans look no different from the young patients. She adds that the patients seem to have confidence in the staff and feel they can really talk to some of the doctors.

At times, however, the physicians rely on the counselors to relate to patients. For Stanford biology major Tim Nichols, it is easy to communicate with the patients because they are in the same age group.

"I can sense their fears or tell if they're withholding information," says Nichols, who is working in the Department of Dermatology this summer and plans to attend medical school when he graduates from Stanford. "I know whether they want to see a doctor or talk with me. It's important to be understanding and sensitive."

STANFORD -- Stanford medical students receive a major part of their clinical training outside Stanford Medical Center.

They can broaden their scope of medicine and caring for patients by working in institutions that range from farm clinics to sophisticated special care centers.

The idea is not new. Several years ago, professors decided there was a kind of in-between clinical experience missing from the curricula of medical schools.

Students were exposed only to the specialized, often complex cases seen in the university hospitals. Someone suggested affiliation with other hospitals, so that students could learn about the common man's lumps and bumps.

When Stanford Medical School was located in San Francisco, it maintained affiliations with local hospitals. When the School moved to the Stanford campus in 1959, the list of hospitals was changed and expanded, but the philosophy continues: enrich medical education and improve the medical care for patients in both institutions.

Today, two-fifths of the teaching at Stanford is done at three affiliated hospitals on the Peninsula, according to an article in the current issue of Stanford M.D., the magazine of the Stanford Medical Alumni Association.

Teaching is conducted in the Stanford Hospital, and at Children's Hospital at Stanford, located on the campus near the School; at Santa Clara Valley Medical Center in San Jose; and at the Palo Alto Veterans Administration Hospital.

In addition, students and residents receive some of their training at the Palo Alto Medical Clinic, at Kaiser-Permanente Medical Center in Santa Clara, Chope Hospital in San Mateo County, and other institutions.

Some receive part of their training in community health centers, such as Alviso near San Jose, Livingston in the San Joaquin Valley, Drew Health Center in East Palo Alto, and in King City.

Stanford students may work in a private doctor's office under his supervision. They also have the option of serving one full-time 6-12 week period literally anywhere, some traveling across the U.S. or Europe.

There are advantages to both the affiliated hospitals and the Medical School. Traditionally, such a system ensures an adequate amount of clinical teaching opportunities for students, and encourages referrals of complicated cases to the School.

"The aim is to provide a spectrum of experience that today no single hospital can provide," says Dr. Irving Schulman, chairman of pediatrics at Stanford.

The community hospital profits from the relationship with the Medical School. "This assures a higher quality of medical care," says former Santa Clara County director of medical institutions, Dr. Norman Nelson.

-more-

The partnership, however, is not always easy. Says Schulman, "We have to recognize that each facility has a different mission. Our mission is to educate, but that is not the mission of Valley Medical Center entirely--it's patient care."

Dr. Daniel Federman, chairman of medicine, stresses the need for continual effort by both parties to approach each other's needs. "There will always be conflicts...it will require constant work. But those are hurdles, not barriers."

Students report that Valley Medical Center often serves as their introduction to primary care, a term used nowadays to describe the patient's first point of contact with the medical system. "There is an amazing amount of work, rather than academic pressure," says David Wells, a recent graduate. At Stanford, students are in the office, do progress notes, lab slips, discuss things. Here I don't remember sitting down."

Despite enthusiasm by both Stanford and Santa Clara medical center for affiliation, further growth of the program may be limited, due to the county hospital's current fiscal concerns, reflected both in government budget cuts and competition from other community hospitals.

"Our prime mission is patient care," explains Dr. Morton Manson, assistant director of medical institutions at Santa Clara. "Teaching is a by-product of that care. We can do so much, but only related to patient care. Properly handled that is an excellent vehicle."

Faculties of Stanford and the Veterans Administration Hospital in Palo Alto are interwoven. The same is true with the interns and residents who rotate there.

At both the VA and at Children's Hospital, professional staff appointments are made on recommendation of Stanford academic chairmen. With a few exceptions, all hold faculty status at the School.

There are currently 68 residents and 9 interns from Stanford on the VA house staff, plus a minimum of 20 students there at all times. Several subjects, like neurology, are taught there.

At Children's, students, house staff and faculty are involved in the care of children with a variety of diseases--hemophilia, rheumatoid arthritis, asthma, cystic fibrosis, cerebral palsy, paraplegia and various birth defects.

In addition, there are efforts to expand the role of affiliation and to cut costly duplication of services. A common system of medical records for both Stanford and Children's is being developed; also, single computer billing in the future; joint use of research computers; more shared work.

The famous Palo Alto Medical Clinic provides students with opportunities to study medicine in the environment of the prepaid group practice. Many of the partners in the Clinic are members of the Stanford clinical faculty.

Students may also choose to serve at community health centers. The center at Livingston near Merced has been most popular, and was established by initial student concern.

In the future, students may serve at the United Farm Worker clinics in Salinas. "Purpose of the training is not only community practice, but also to learn how the medical system is working," says Dr. Count Gibson, chairman of community and preventive medicine.

Students also work with private doctors or have the opportunity to broaden their scope of medicine by serving in a hospital elsewhere in the U.S. or abroad.

One student, after a stay in Appalachia, reported "dissatisfied patients, missed diagnoses, shotgun therapy, and psychoneurotic doctors.... There is nothing like direct experience to put it in concrete terms."

STANFORD -- A new radiotherapy technique to treat an eye condition called Graves' ophthalmopathy has been reported by physicians at Stanford University School of Medicine.

In a study of 23 patients, 65 percent responded in an excellent or good manner to the radiation treatment, and no patient was made worse by it.

The study appears in the August issue of the Journal of Clinical Endocrinology. Investigators are Drs. Sarah Donaldson; Malcolm Bagshaw, chairman of the Department of Radiology; and Joseph Kriss, head of the division of nuclear medicine.

Their work was supported by grants from the National Institutes of Health in Bethesda, Maryland.

Graves' disease is a common disorder that can occur at almost any age. It is usually associated with overactivity of the thyroid gland. A complication of the disease is an eye condition that can cause a variety of problems, including protrusion, swelling, double vision, and loss of vision.

The most characteristic feature of the ophthalmopathy is a massive enlargement of the muscles that control the eye, pushing the eyeball forward. This abnormality is thought to be caused by a local hypersensitivity reaction involving lymphocytes (white blood cells) which build up in the small, precisely controlled muscles, according to the researchers.

Radiotherapy has been used sporadically in the last 40 years for treating Graves' ophthalmopathy, but not with very prompt or favorable results, said Kriss. He attributes the success at Stanford to improvements in technique and equipment.

Over a two-week period, the affected eye muscles are irradiated daily by a finely directed beam from a medical linear accelerator. "The beam is designed to avoid scattered radiation that could damage the lens, cornea, or other surrounding eye tissue," explained Kriss. He added that the field of treatment does not include the pituitary gland, which was often irradiated in the past for this condition.

The investigators believe that radiation suppresses the immune reaction, which involves the white blood cells accumulating in the ocular muscles. Improvement may occur even before the treatment is finished, and appears to be long lasting. The amount of radiation is much lower than the dose administered to treat cancer patients, Kriss point out, and is well tolerated by adults.

Corticosteroid therapy is also used to treat Graves' ophthalmopathy. However, the drug has various side effects, Kriss continued, and symptoms often return as soon as the drug is stopped. In the Stanford study, nine patients who had responded poorly to corticosteroids, were subsequently treated successfully by radiotherapy.

The 23 patients were studied at Stanford between 1968 and 1972, and ranged in age from 30 to 60. They included approximately an equal number of men and women, although Graves' disease is six times more common in women, noted Kriss.

None of the patients treated had any evidence of spontaneous improvement before the start of radiotherapy. They were hospitalized throughout the treatment period and examined frequently. Eye changes before and after radiotherapy were clinically evaluated, as well as numerically scored.

Seven patients showed an excellent response to the treatment; eight had a good response; six, a fair response; and two had no response or change. Another 12 patients treated since the study responded in about the same ratio, Kriss said. Only one mild relapse has occurred.

STANFORD -- The Stanford University School of Medicine will embark on a new residency training program in primary care for internists and pediatricians, Dean Clayton Rich announced Tuesday (Aug. 7).

He said the Department of Health, Education and Welfare has awarded a $210,400 contract to Stanford to develop a model graduate training program in primary care, utilizing a team approach to the delivery of family health services.

The program would qualify trainees to take board examinations for certification in internal medicine or pediatrics.

Stanford intends to admit at least 12 trainees in the program during the three-year period of the contract, including four part-time residents in the first year. Eventually, the School will have two trainees in medicine and two in pediatrics in each year of the three-year program.

"Training primary care-oriented internists and pediatricians is as crucial as training family physicians," said Dean Rich. "A significant amount of primary care in the United States is already being rendered by these specialists.

"Historically, these two groups have never had a model in which they could view and care for families in a complementary fashion."

Dr. Rich added that the present programs for training internists and pediatricians are hospital-based and that there is a need for innovation in relating to the roles of these two specialties in the delivery of health care.

The HEW contract was authorized under the Comprehensive Health Manpower Training Act of 1971, and awarded by the Bureau of Health Resources Development of the Health Resources Administration.

Similar contracts to foster the training of primary care physicians have been awarded by HEW to the Boston City Hospital, and to Washington University School of Medicine in St. Louis.

STANFORD -- Potential encounter group participants should recognize both the promise as well as the limits of the encounter technique, according to a new book, co-authored by a Stanford University psychiatrist.

Such groups can present clear danger to participants if handled improperly, or they may be extremely effective.

These conclusions were reached after a three-year systematic evaluation of encounter groups, reported in the book Encounter Groups: First Facts. The authors are Irvin Yalom, professor of psychiatry at Stanford University School of Medicine, University of Chicago Psychologist Morton Lieberman, and State University of New York Psychologist Matthew Miles. The book is the first scientific study of the encounter movement.

Encounter groups attempt to provide an intensive, high contact experience, encouraging open, interpersonal confrontation, self-disclosure, and strong emotional expression. Generally the goal is some kind of personal change--of behavior, attitudes, values or life-style, say the authors.

The scientists evaluated 17 varieties of encounter groups, including Gestalt therapy, psychodrama, Synanon, and non-verbal. They enlisted the aid of 206 Stanford students who wished to participate in encounters. Groups were led by professionals, either psychiatrists or clinical psychologists, and consisted of 12-13 participants each, both men and women.

The investigators found that a third of the subjects showed positive changes, whereas approximately two-thirds found the experience to be unrewarding, either dropping out, gaining little from the encounter, or experiencing significant psychological harm.

Sixteen participants who were termed "casualties" developed adverse effects which ranged from psychoses and severe depression to students whose self-esteem was lowered. According to the authors, casualties were defined conservatively, only if there was evidence of psychological harm six to eight months after the group ended.

Though prominent encounter group practitioners and organizations have reported minimal negative effects on members, the authors state that they found group experiences damaging to eight percent of those who began the groups, "a figure which most people would not consider safe." Previous studies, they say, have tended to minimize negative effects, and such groups are not as safe as they have claimed.

Furthermore, the study found that persons who came to the groups with strong wishes and hopes for change, and considered the groups to be "safe," were rather more likely to be at risk, more vulnerable to unexpected attack and rejection. Persons who came with equivalently strong hopes and moderate skepticism were likely to learn a good deal, the authors report.

The most surprising finding of the study, says Yalom, is that the most successful groups focused on the participants' understanding of the encounter, rather than just experiencing it. The type of encounter group was found not to be as important as how the group was led, and if the leader provided a supporting framework for the participant to understand his experiences. The common anti-intellectual belief of encounter groups, "feeling, not thought," should rather be "feelings, only with thought," suggested the scientists.

-more-

"Let it all hang out," they suggest, might be more properly revised to "let more of it hang out than usual, if it feels right in the group, and you can give some thought to what it means."

Another common myth is that enthusiasm makes for change in the encounter group setting. The investigators found instead that enthusiasm must stand the test of time, and that if real learning has occurred, it will be kept.

Some groups in the Stanford study were shown to be extremely effective, with participants experiencing significant personal growth and change six months after the groups ended.

"Encounter groups excel in their ability to involve and provide a setting in which certain basic human activities associated with productive change can occur.... The ability of such groups to provide a meaningful emotional setting in which individuals can overtly consider previously prohibited issues, cannot be ruled out as an important means for facilitating human progress," the investigators say.

However, the authors warn, "encounter groups present a clear and evident danger if they are used for radical surgery in which the product will be a new man." Findings of the study encourage the person considering attending such a group to determine realistically his expectations of the group.

"A person who feels, essentially, that he or she is in psychological distress should ordinarily be considering counseling or psychotherapy rather than an encounter group experience."

Dr. Yalom is associate director of the psychiatry clinic and director of the group therapy program at Stanford. He has authored the book, The Theory and Practice of Group Psychotherapy, and numerous articles on group therapy.

Editors: Writers interested in attending the conference should notify the cardiology division at Stanford University School of Medicine (415: 321-1200, ext. 6823). The conference is not open to the public.

STANFORD -- An International Conference on Biomedical Electrode Technology, sponsored jointly by the cardiology division of the Stanford University School of Medicine and the NASA-Ames Research Center, will be held at Stanford September 13 and 14.

"The purpose of the conference is to bring together various major contributors in the field of biomedical electrode technology for discussion of recent advances," said program chairman Harry Miller, administrator of Stanford's cardiology division.

The session will focus on four main areas--materials sciences; physics and engineering; research clinical applications; and flight applications and future directions.

The keynote speaker will be Dr. Charles A. Berry, director of life sciences for the National Aeronautics and Space Administration.

All sessions and exhibits will be held in the Bishop Auditorium of Stanford's Graduate School of Business.

STANFORD — Dr. Thomas C. Merigan, professor of medicine and head of the division of infectious diseases at Stanford University School of Medicine, has been named winner of the annual Borden Award for outstanding research from the Association of American Medical Colleges (AAMC).

The award was announced Tuesday, Sept. 25, by Dr. John A.D. Cooper, president of the AAMC. It will be presented to Dr. Merigan Nov. 6 at the AAMC's 84th annual meeting in Washington, D.C.

Dr. Merigan was cited for his pioneering work on interferon, a protein produced by body cells in response to virus infection. Earlier this year he and three British scientists reported they had successfully used interferon to prevent common cold infections in human volunteers.

The findings indicated that interferon could have future usefulness as a preventive remedy for cold and other viruses. Currently it is too costly to produce and administer to be a practical remedy, but efforts are underway to develop simpler and less expensive techniques.

A prolific writer and researcher, Dr. Merigan has made numerous other contributions in the fields of molecular biology, virology, and human genetics.

The San Francisco native obtained his B.A. (1955) and M.D. (1958) degrees from the University of California. Before joining the faculty at Stanford in 1963, he was a clinical associate at the National Heart Institute in Bethesda, Maryland.

The Borden Award, presented annually since 1947 by the AAMC in cooperation with the Borden Company Foundation, is given in recognition of "outstanding research in medicine conducted by a member of the faculty of an affiliated college." The award consists of $1,000 and an inscribed gold medal.

Last year's winner was Dr. George C. Cotzias, professor of medicine at the State University of New York, Stony Brook, and professor of neurology at Mount Sinai School of Medicine. He was cited for findings which established L-Dopa as therapeutic treatment for Parkinson's Disease.

STANFORD -- James H. Stanford has been named director of finance for the Stanford University Medical Center.

Stanford, finance director of the San Jose Hospitals and Health Center, Inc., for the past three years, will assume his new duties October 15.

The appointment of the 35-year-old executive was announced Monday (September 24) by Dean Clayton Rich.

Stanford will head a newly formed office consolidating the major financial activities of the Medical Center. The office will serve the needs of the School, the Hospital, and the Clinics.

The new office will be located in the Administrative Annex on Quarry Road.

Stanford is a former associate director of Stanford University Hospital, and also worked in the Dean's office of the Medical School.

He holds A.B. and M.B.A. degrees from Stanford University. He and his wife and two daughters reside in Portola Valley.

Science Writers: The embargo date on this story is dictated by the scientific presentation of this work at the meeting of the American Academy of Ophthalmology and Otolaryngology in Dallas, Texas, Sept. 19. Photo available if not included with story.

ADVANCE FOR P.M. RELEASE WEDNESDAY, SEPT. 19, 1973.

STANFORD -- Screening newborn babies for deafness is a 24-hour operation at Stanford University Hospital, but it is all done by machine.

A unique automated system called the crib-o-gram detects infant movement in the crib and records any changes when a test sound is turned on. Over the past three years, 180,000 tests have been administered to 6,000 babies in the Stanford nurseries.

The procedure was developed to meet the challenge of detecting hearing loss and deafness early in life, long before the parents or physician would normally suspect a problem exists.

Results so far have been encouraging. Eight babies who failed the test at birth were confirmed by additional testing at six months to have hearing losses. Treatment for them has begun before the age of one, giving them a better chance to live a fuller life in a sound-filled world.

The findings were reported today (Wednesday, September 19) by the crib-o-gram's developer, Dr. F. Blair Simmons, head of the division of otolaryngology at Stanford University School of Medicine. They were presented at the 78th annual meeting of the American Academy of Ophthalmology and Otolaryngology in Dallas, Texas.

Simmons' work was done with the help of Frederica Russ, research assistant. It was supported by a grant from the National Institute of Neurological Diseases and Stroke of the National Institutes of Health in Bethesda, Maryland.

"Hearing rehabilitation is most successful if it is begun around six months of age," said Simmons. "Yet very few children with hearing defects are discovered before they are one. In fact, most problems are not detected until children are two or three, when their language development falters. Testing hearing at birth or soon after can improve the chances of normal speech and language development," he noted.

The heart of the automatic system is an inexpensive motion detector called a transducer. It was originally developed to register the fuel load in aircraft by the amount of weight stress on the wing supports. When mounted on the crib frame, it detects the stress caused by movement in the crib.

The device monitors motion before, during, and after a test sound is emitted from a microphone in the ceiling of the nursery. It is so sensitive, it can detect breathing, heart beats or hiccups.

Activity is recorded on a paper tape which is scored during normal working hours. Since the crib-o-gram is a pilot project, scoring is done by individuals, but a computer could do it as completely, Simmons pointed out. "It is simply a matter of determining whether there has been a change in crib activity after a test sound."

-more-

The likelihood of a positive test response independent of spontaneous movements, nursery routines and changes in arousal level depends on the infants' level of consciousness. Tests are most accurate when infants are lightly sleeping according to the investigators, and least dependable when they are fully awake and active or deeply asleep and dreaming.

At Stanford, the best time to obtain positive responses is between 3:00 and 4:00 a.m., said Simmons. However, he stresses that it is important to test infants repeatedly at different times throughout their nursery stay for a valid response rate.

An index of infants' response rates to account for spontaneous movements unrelated to the test sound is computed periodically by running a test without sound. The scorer, who does not know when a test has been silent, scores it the same way as a regular test. Scoring criteria are revised from the results of the random rates.

Criteria for passing and failing the test have been developed through a control study of 5,000 babies in the Stanford nurseries between October 1970 and April 1973. Infants are considered to hear if their response rates are better than 20 percent, or if there are two distinct arousal responses within two seconds after the test sound.

The average response rate of those in the study who passed was 36 percent. Pediatricians of every infant tested have been requested to notify Stanford if any hearing problems develop later. But in a follow-up study of two-year-olds who passed the test, there have been no reports of deafness.

A total of 327 babies who failed the crib-o-gram were asked to return to Stanford or another facility at six months for further screening. Eight of those babies were found to have hearing defects.

The incidence of deafness in newborns is one or two per thousand, according to Simmons. Since it is a relatively small ratio, nursery staff or pediatricians do not always feel it is worth their time to screen every infant individually, he said.

"With the crib-o-gram, little extra time or effort is involved," explained Simmons. "Everything can be mechanized, and the average cost is 85 cents per child."

The equipment is set to test each of four rooms of the well-baby nursery 20 times a day. It turns on, simultaneously monitors all cribs in a room, switches to another room and then shuts off after every room has been tested until a timer begins the next cycle.

Although the system monitors the 32 cribs in the Stanford nursery, it is capable of testing 600 babies an hour throughout the day, Simmons said. Each crib is identified for the recorder unit by a digital code.

For babies in the premature and intensive care nurseries who require more individual care, Simmons has designed a small, portable unit that can be used with any type of crib, including an isolette. Infants as small as three and one-half pounds have been successfully tested.

The transducer is placed under the mattress and a small microphone is clipped to the crib. Before infants are discharged, a test sequence is recorded hourly for 24 hours. Results are processed as in the larger system, but there are no silent tests to check spontaneous responses. This smaller unit is also being tried by hospitals in Boston, Denver and Pittsburgh.

A considerably larger population and consistent follow-up are needed to determine exactly how reliable the crib-o-gram is, said Simmons. Nevertheless, the system can detect hearing defects in newborns, and at this stage it appears to be the most effective mass screening technique available for infants.

STANFORD -- Cancer research at Stanford University has received a major boost through federal grants totalling $3,388,000, the National Cancer Institute announced Tuesday (Sept. 11).

The grants, ranging from three to five years, will support efforts to improve understanding of cancer and methods of cure.

The largest grant of $2,461,000 to Dr. Henry S. Kaplan will provide continuing basic support to the Stanford cancer research facilities in the Division of Radiobiology, where more than a dozen senior scientists are engaged in radiobiology research, radiation treatment, and training of new personnel.

Kaplan, the Maureen Lyles D'Ambrogio professor of radiology, is noted for his studies in mouse leukemia and as a leading exponent of the use of supervoltage radiation therapy.

Other recipients and grants include:

Dr. Lewis Aronow, professor of pharmacology, $193,000 for studies related to the use of steroid hormones in cancer chemotherapy;

Dr. J. Martin Brown, assistant professor of radiology, $241,000 for the study and development of radiosensitizing compounds which may some day play an important role in the treatment of cancer;

Dr. Bruce Hudson, assistant professor of chemistry, $101,000 for studies to improve an analytical method for the detection of circular DNA, the genetic material of viruses believed to be associated with animal cancers;

Dr. Robert F. Kallman, professor of radiology, $226,000 for studying the mechanisms of radiosensitivity in normal and tumor cells; and

Dr. Kendric Smith, professor of radiology, $166,000 for studying the mechanisms by which radiation kills cells, and the way irradiated cells repair themselves.

STANFORD--A Stanford University professor thinks medical schools must develop a new type of faculty which takes the teaching of medicine and the care of patients as serious assignments.

"The flowering of federally supported biomedical research in the past 20 years has not been an unmixed blessing," says Dr. Daniel Federman. "Combined with social factors it has contributed to two problems which now beset medical schools.

"One is an inattentiveness to health care delivery, the other is the denigration of clinical teaching."

Federman said that as research in departments of medicine became more fundamental, it has tended to draw the faculty further away from the patient.

"In brief, because of their often minimal role in a clinically responsible capacity, they risk becoming amateurs," the Stanford professor said.

He added that this is the more worrisome because clinical care in the hospital has become much more time consuming, complex, and dangerous.

Federman made his remarks in an article in the current issue of the Harvard Medical Alumni Bulletin. A Harvard medical graduate, he is professor and chairman of the department of medicine of the Stanford University School of Medicine.

He proposed that along with research-oriented faculty, the medical schools should develop faculties which will specialize in the teaching and practice of medicine from a scientific base.

To foster this development, a school has to provide unambiguous signals to young people by the appointment and promotion of people with clinical interests, Federman recommended.

"I feel good teaching can be learned," he said. "Rather than assuming teaching skill in the faculty, I believe it should be part of their training, and be both taught and evaluated.

"For two decades our model has been the person excellent in three areas of patient care, teaching and research. But triple threats are as rare in medicine as in football."

Medical schools, according to Federman, have been reluctant to define standards of teaching quality. As a result many of them have denied themselves of some of their best graduates who would have been interested in a clinical teaching career.

-more-

This is because research generates new knowledge which is published and recognized at a distance, Federman said. The teaching and clinical activities of any school do not easily generate a distant reputation.

Federman said the curriculum and clinical exercises are but a small part of learning for the future doctor. Equally important is the teacher's performance as a physician from whom the students learn how to achieve the blend of science and humanism that characterizes the excellent doctor.

"If you have watched a teenager who likes rock music," wrote Federman, "you know that as soon as she turns on the radio and hears just two bars of music, her foot is tapping, the hands are beating, her chin is bobbing and she's singing.

"She knows every note, every word--and she was never taught it. She has learned without being taught, and a whole pattern of response is cued by the briefest stimulus."

Turning to the future of medicine, Federman suggested that every hospital can and should become a learning hospital "because doctors must continue to learn or else abdicate their goal of providing the best care for every patient."

"Every day of the physician's life should be a learning day," he wrote. "It doesn't matter what hospital you are in, it ought to be a place to learn.

"Thinking of every hospital as a learning hospital would enable us to provide the right intellectual response to the new stress on peer review, on audit, on vouching for the quality of what we do, and on studying and assessing the quality of care.

"But it will only work when the self-demand for clinical excellence is established in the student during medical school."

To attract clinician-teachers, Federman said, universities must stop judging clinicians on the same basis they judge the work of history professors.

"The department of history has to teach history and do research in history, but it doesn't have to make history," he said. "But the clinical departments must do clinical work in order to foster pertinent research and to provide the proper teaching environment."

STANFORD -- An expansion of patient care, training and research activities was announced today by the Communications Disorders Center at Stanford, a joint program of the Children's Hospital at Stanford and the Stanford University Medical Center.

The expansion coincides with the Center's move into new, more spacious offices at 600 Willow Road, adjacent to Children's Hospital, said Dr. Kathryn Beadle, director of the Center.

Beginning this month, Dr. Beadle said, the Center will focus on four new projects: an experimental class for pre-school children with speech and language disorders; an expanded training program for interns from California State University at San Jose and San Francisco; research plans concerning possible new diagnostic and treatment methods; and assumption of responsibility for patients who were treated previously at the Scottish Rite Institute for Childhood Aphasia at Stanford.

The Aphasia Institute, established at Stanford in 1962, has moved to California State University at San Francisco.

"All services begun under the auspices of the Aphasia Institute will be continued at the Communications Disorders Center," Dr. Beadle said.

The Center's pre-school class, supported by a $10,000 grant from the Luke B. Hancock Foundation of Menlo Park, begins September 17. Its purpose, Dr. Beadle said, will be to increase and improve the children's verbal language skills so they will be better prepared to enter school.

The class will include 10 children ranging in age from 3-1/2 to 5-1/2 years, she said. There are still openings for two children in the class.

Also beginning later this month, Master's Degree candidates in communications disorders from the state universities at San Jose and San Francisco will serve internships at the Center.

The Communications Disorders Center at Stanford was established in 1971, when the Medical Center, Children's Hospital, and Palo Alto Medical Clinic agreed to consolidate their speech and language diagnostic and treatment programs.

The current expansion of services is another step in eliminating costly duplication and achieving improved coordination and efficiency in the delivery of health care, Dr. Beadle said.

The Center's staff of eight speech and language pathologists and one special education teacher handle about 8,000 patient visits per year.

Diagnosis and treatment is provided for all types of speech, language and voice disorders in patients aged 18 months to geriatrics. Services are also provided in a satellite unit at the Palo Alto Medical Clinic.

STANFORD -- Stanford University medical researchers have developed an instrument which permits them to take a small sample of heart tissue from a living patient and study it for evidence of rejection or heart disease.

The instrument, called a bioptome, was pioneered by Japanese physicians 10 years ago, but very few doctors in the West have used it.

Working with Werner P. Schulz, a Peninsula engineer who specializes in microsurgical instruments, Stanford researchers have developed a new bioptome which is shorter and more flexible than the original.

The bioptome is essentially a piece of wire with a clipper at the end. It is inserted into the patient's jugular vein and threaded down into the heart, where it takes a small sample of cardiac tissue. The procedure is done under local anesthetic, and the insertion is viewed through a fluoroscope.

At Stanford the instrument is now used routinely to obtain tissue specimens from patients following heart transplantation, and to make a direct diagnosis of rejection--a common problem in transplants. Previously, the doctors made their diagnosis by studying the electrocardiogram and clinical signs.

The report of the new development appears in a recent issue of the Journal of the American Medical Association. The authors are Drs. Philip K, Caves, Edward Stinson, Anthony F. Graham, Margaret E. Billingham, Todd M. Grehl, and Norman E. Shumway.

"The virtue of the bioptome," Dr. Shumway explained, "is that it permits direct judgment, based on tissue study, of the rejection reaction."

In particular, he said, the bioptome samples help avoid excessive use of drugs to combat the rejection reaction. This is important because the drugs cripple the body's immunological defenses and thus open the way for infections.

Caves, who is now a lecturer in cardiac surgery at the University of Edinburgh, reported that up to now studies of the transplanted heart in living patients have been limited by the lack of a simple, safe biopsy technique.

Caves and his collaborators first tried the new bioptome in transplanted dogs and found they could obtain excellent tissue specimens for microscopic studies.

He subsequently tested the instrument in 10 heart transplant patients, obtaining 20 biopsy specimens "The specimens were valuable in diagnosing acute rejection episodes," he said. "All the patients tolerated the procedure well and there have been no complications."

Stanford physicians, Caves said, plan to apply the new technique to the study of other forms of myocardial disease.

He did the work while at Stanford under fellowships from the British Heart Foundation and the American Heart Association. (Pictures available on request if not included.) Mailed September 5, 1973

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 321-5310

STANFORD -- Dean Clayton Rich of the Stanford University School of Medicine thinks that a bill banning experiments on human fetuses will jeopardize efforts to insure the delivery of healthy babies in the future.

"I understand the benevolent motivation for the bill, but it is more harmful than beneficial," he said.

Rich said the legislation could interfere with future efforts to learn about human development.

He noted that studying the physiology of the fetus is important because neonatal mortality still remains disappointingly high.

"We need new knowledge to insure the maximum health and well-being of every pregnant woman and newborn child," Rich said.

The dean made his comments in a letter sent to the Assembly Committee on Health, and released Friday (Aug. 31).

A bill, authored by Sen. David Roberti, D-Los Angeles, cleared the Committee on Thursday on an 8 to 0 vote. It would deem experimentation on human fetuses to be unlawful and unprofessional conduct.

Apparently, the bill passed after a witness told of alleged "cruel acts" performed on human fetuses at Stanford Medical School, according to United Press International.

Rich disputed the testimony of James Babcock, a premedical student from the University of California. The testimony was given before the Senate Judiciary Committee and repeated, in part, yesterday.

Babcock, according to Rich, visited Stanford in 1972 with members of the Student Pro-Life Federation.

The student could not have witnessed the described procedures at Stanford because the project had been terminated in 1969, Dean Rich wrote. Babcock could only testify to his interpretation of remarks made by Dr. Robert Goodlin, an associate professor of gynecology and obstetrics.

-more-

Dean Rich defended Goodlin's work "as essential to insure the delivery of healthy babies in the future. The legislation before the committee would prevent such research."

In a separate letter, Dr. Goodlin said that in all studies related to human fetuses, anesthetics were used for humane benefits and to protect the fetus.

He said his purpose was to develop an artificial environment in which a baby could be maintained alive through artificial rescuscitation and feeding of nutrients.

Dr. Philip Sunshine, in written testimony, said progress in the treatment of respiratory distress syndrome, the disease that killed the late President John F. Kennedy's son, could not have been made without techniques developed in conjunction with fetal research.

Sunshine, a Stanford pediatrician, argued that the issues are so sensitive and so important they require an informed judgment on the benefits and risks of such experiments, rather than a ban on all research.

He proposed creation of a committee made up of clergymen, informed laymen, legislators and scientists to review the issues and formulate "a thoughtful approach" to the problem.

"Stanford and other university premature centers are constantly on the forefront of medical practice to save babies that only yesterday would have died," Sunshine said. "We feel your legislation goes to the very heart of such research and, in fact, may foreclose it."

Dean Rich said the complex ethical problem of research on human fetuses now is under review at the national level.

"This review will undoubtedly result in an analysis of the issues and a policy that could be exceedingly useful in considering legislation that would be most beneficial in this State," he said.

The bill, approved by the Assembly Committee on Health, deleted a provision banning human conception outside the womb.

Stanford physicians had opposed this provision as foreclosing research in infertility.

STANFORD--Two noted professors have joined the faculty of the Stanford University School of Medicine. They are Drs. William Agras, a psychiatrist well known for his work in behavior modification, and Dr. John Nicholls, a neurophysiologist concerned with the relation of the central nervous system to behavior.

Their appointments, effective October 1, were announced by Dr. Clayton Rich, vice president for medical affairs and dean of the Medical School. Dr. Agras is professor of psychiatry, and Dr. Nicholls is professor of physiology.

Former professor and chairman of psychiatry at the University of Mississippi Medical Center, Dr. Agras is an authority on using behavior modification to deal with psychiatric problems. The approach involves helping a patient change his environment or behavior to alleviate symptoms, instead of attempting to understand the causes of his problem through psychoanalysis. The technique was endorsed this year by the American Psychiatric Association.

Dr. Agras, author of numerous scientific publications, is on the editorial boards of several professional journals and is the 1974 editor of the Journal of Applied Behavior Analysis. He has also served on a variety of local and state committees concerned with enhancing mental health services.

A native of England, Dr. Agras, 44, graduated from the Middlesex Hospital Medical School in London, in 1955. Following a year of training in England, he became a psychiatry resident in Canada, first at Montreal General Hospital and then at Montreal Children's Hospital.

From 1959 until 1961, he was a teaching fellow in the Department of Psychiatry at Montreal General Hospital. He subsequently served on the faculty of the University of Vermont College of Medicine for eight years, from 1961 until 1969, when he went to Mississippi.

A neurophysiologist, Dr. Nicholls is interested in how nerve cells work together to produce organized behavior. His studies of the basic mechanisms in central nervous systems in lower animals have contributed to the understanding of the more complex nervous systems of mammals.

Dr. Nicholls, 43, was previously associate professor of neurobiology at Harvard Medical School. Since 1971, he has also been an adjunct fellow of the Salk Institute. He is author of several research publications.

Born in England, Dr. Nicholls received his Ph.D. in physiology in 1955 from London University. After serving as casualty officer at Charing Cross Hospital in London for a year, he did research in physiology at University College, London and at Oxford.

In 1962, he became a research fellow in neuropharmacology at Harvard Medical School. Three years later he joined the faculty of Yale University School of Medicine as associate professor of physiology, where he remained until returning to Harvard in 1968.

STANFORD--Astronomical medical malpractice verdicts and skyrocketing insurance premiums for physicians are making the California malpractice picture rather desperate.

A leading consultant to physicians on legal-medical questions, Dr. David S. Rubsamen of Berkeley, who holds both medical and law degrees from Stanford, says the most alarming trend in malpractice suits is the size and frequency of awards.

There have been six medical malpractice awards in California in excess of $1 million--four of them within the last 20 months.

"The public cannot help but be impressed by these verdicts. They not only make a million dollars or more for serious disability seem reasonable, but awards in less severe cases will tend to be inflated as well," Rubsamen said in an interview for the current issue of Stanford M.D., magazine of the Stanford Medical Alumni Association.

He cites the difficulty of insuring physicians, particularly those in high-risk specialties, whether they have had suits against them or not.

In addition, the number of malpractice claims against doctors is increasing at a rate of 15 to 20 percent annually, he says.

Changing sentiment among jurors during the last few years has intensified the problem for doctors. Five or six years ago, says Rubsamen, cases of exceptionally complex medical facts probably would have been won by the defense. Juries in those days seemed reluctant to second-guess medical decision-making, particularly in metropolitan areas. Recently juries have been more willing to find for the patient-plaintiff in complex cases.

Rubsamen foresees further changes in the malpractice picture as the California Supreme Court's recent "informed consent" decision is enforced. This ruling states that the patient has a right to "all information relevant to his decisional process." The patient must be told of alternate treatment methods, unless he requests not to be told.

The patient has the right to decide whether to accept one treatment or another, or to forego treatment because he is unwilling to face a possible complication.

The court has also said that a private physician may not delegate significant responsibility for the care of his private patient without that patient's specific consent.

Rubsamen emphasized that it is not enough for the doctor to tell his patient that a resident of a teaching hospital will be "on the team" cooperating in his treatment. The patient must be made aware that the resident will be performing the operation.

With the prospect of rising awards and increased legal actions, Rubsamen has studied the question of no-fault liability in medical malpractice, and he determined that in the end that system would be as accusatory as the present system.

-more-

Taken literally, he says, a no-fault system means payment for every unanticipated disability resulting from medical intervention or omission. The slightest evidence of medical oversight would "ring the compensation bell."

Under a no-fault system, Rubsamen says, "there would be pressure for defensive medicine far in excess of anything we have today." He cautions that we could end up trying to define ideal care, and paying compensation to any patient who suffered for lack of it.

Instead, the doctor-lawyer suggests another approach: eliminating the jurors, the courtroom, and the judge. With arbitration, an informal hearing would be held in a small office before an arbitrator agreed upon by both defendant and plaintiff.

The arbitrator's decision is usually final, with laws limiting appeal. Advantages, says Rubsamen, would be privacy for both doctor and patient, and quick disposition of cases.

Arbitration, he says, would put a lid on skyrocketing awards for the patient-plaintiff. However, there is also more assurance of a decision for the patient with a relatively trivial disability which an attorney may not otherwise decide is worthwhile to pursue.

Rubsamen feels that the most effective legal reforms over the next 10 to 20 years will be procedural: trial before a judge, select panel, or arbitrator.

STANFORD--Stanford engineers are developing an instrument that will harmlessly take pictures of organs inside the human body, using sound instead of light or X rays.

The device is expected to be immensely valuable in medical diagnosis, particularly in cardiology, in abdominal surveys for tumors, in ophthalmology, and in obstetrics when X rays may be harmful.

The Ultrasonic Imaging System (ULISYS) is being developed by Stanford Electrical Engineering Professor James D. Meindl, director of the Stanford Electronics Laboratories, and a team of collaborating engineers and doctors.

The ultrasonic "camera" consists of a cylindrical tube, about 24 inches long, which is connected to a control apparatus and display screen. It works by aiming a concentrated "bundle" of high frequency sound waves at an organ, such as the heart. The echoes produced are processed to form a picture similar to a television image.

The ultrasound waves generated by ULISYS are harmless and cannot be heard, since the pitch or frequency is above the range of human hearing. (The ear can hear sounds between 100 and 20,000 cycles per second; ultrasound in ULISYS is at 3 million cycles per second.)

Because it is a harmless procedure, Dr. Meindl foresees the ULISYS becoming a standard examining tool in pregnancy. He describes the procedure as quick, accurate, and low cost.

In cardiology, the kind of information supplied would not ordinarily be available. In part it can be obtained with the use of catheterization and other invasive procedures which entail hospitalization and potential risks to the patient. (Catheterization involves passing a small tube into a vein in the arm and through the blood vessels into the heart.)

The ULISYS can picture the heart in continuous action as seen on a television screen.

Dr. Meindl notes that sound waves are particularly suited to carrying such images, since they travel well through solids, and particularly well through liquids, which make up a high percentage of the human body.

Ultrasonic diagnosis is an established clinical technique in several medical areas, such as obstetrics, gynecology, and cardiology. To date, however, it has been limited almost exclusively to use of a single, pencil-like beam or signal which is echoed back to a receiver. In this way the depth of a particular structure can be determined.

In ULISYS, however, many sound beams are emitted, then processed, to form a more real, two dimensional, picture of the structure.

-more-

222--ULISYS

Ophthalmologists are currently using a pencil-like beam of ultrasound to search for disease states and foreign bodies in the eye. In the future, with use of ULISYS, they will be able to obtain a more thorough and accurate picture.

According to Dr. Meindl, the unique instrument is more than two years away from being available as a commercial device for use by doctors.

He, and collaborators Drs. James Plummer, Maxwell Maginness and others, are at work on improving the resolution--or clarity--of the reflected image, on making larger fields of view possible, and on improved television displays.

The engineers see the instrument as a valuable complement to X-ray procedures, enabling doctors to see pictures, like that of the heart, not possible with radiation techniques.

Besides medical applications the instrument may find testing uses, as in detecting an interior flaw in a metal object such as a propeller blade. It may also find uses, says Meindl, in underwater imaging.

STANFORD--Stanford University Hospital has embarked on a campaign to discourage smoking. Signs that read "thank you for not smoking" have been posted in patient care areas.

"In a polite fashion, we are trying to dissuade people from smoking in patient care units," said Dick Pettingill, assistant director in Nursing Services, who is coordinating the campaign. "We hope that employees and visitors will abide by the suggestion and confine their smoking to lounges or solariums outside the patient units."

For patients bothered by smoking, the Hospital provides a sign they can hang on the door or above the bed to indicate they would prefer not to have their visitors smoke in the room. The sign consists of the international stop logo with a burning cigarette in the middle.

The campaign will eventually be extended throughout the Medical Center, according to Pettingill. For some time, sales of cigarettes have been prohibited within the Medical Center and the Hospital gift shop is phasing out its inventory of cigars and tobacco.

STANFORD--A group counseling program for dying patients has been launched by a psychiatrist at Stanford University School of Medicine.

The service, begun three months ago, is designed for a small group of patients who are aware they have a life-threatening illness or an illness which will shorten their life span, said Dr. Irvin Yalom, professor of psychiatry at Stanford.

"The group provides a place where these patients can talk openly and share their thoughts on dealing with the prospect of death as well as the optimal ways to live the rest of their lives," Yalom said.

"In many respects, the real focus is on living," he continued. "Facing the prospect of death can help these patients achieve a new perspective on life and perhaps re-cast their remaining life in a different and more gratifying way."

Yalom noted that death is in many respects a taboo subject in our society.

"These patients welcome having a forum where they can talk about topics which are often taboo," he said. "Usually, they have to keep these things to themselves, since the outside world believes they don't want to talk about them."

At the same time, the psychiatrist said, patients themselves are often reluctant to discuss their thoughts about death with others.

"The patients feel they shouldn't put an additional burden on relatives in their grief," he said. "They're also afraid that talking about it will drive away doctors and nurses.

"So, in effect, there is a mutual misunderstanding. What results is a conspiracy of silence about the subject of death."

Because of this, Yalom feels the group counseling service "can have a real benefit."

Patients in the group have wanted to discuss many things, including their own thoughts about death, the effect of their condition on their families, ways of overcoming feelings of isolation, and the best ways to utilize their remaining life span.

Yalom, who has many years of experience in group therapy, has "no set doctrine" he wants the participants to adopt.

"I'm not trying to strip away patients' defenses," he said. "But many people believe that it's possible to face death openly and courageously. This allows one to face death with dignity, instead of the usual silent conspiracy about someone dying."

Up to this point, doctors have reacted somewhat unenthusiastically to Yalom's program, but he feels this reaction is understandable.

"To some extent, doctors are threatened by the dying patient," he said. "In many cases, the physician backs off and tries to avoid the patient. He fears his own failure, and fears there is nothing more he can do. He believes his presence is unwanted by the patient, when, in fact, the patient really wants him there."

Yalom expects to keep his group down to a half-dozen persons, although additional groups may be added if the need arises. Patients can be self-referred or referred by physicians.

ADVANCE FOR P.M. RELEASE WEDNESDAY, OCTOBER 24, 1973.

STANFORD--An enzyme test, until recently used for research, can now be applied to the diagnosis of heart attacks which cannot be detected by the electrocardiogram, a Stanford University pathologist reported Wednesday (Oct. 24).

The enzyme, called creatine phosphokinase (CPK) plays an important role in the energy storing mechanism of tissues.

Scientists have known for some time that a rise of total CPK in patients' blood serum is associated with heart attacks. But because abnormal values may be caused by a multitude of other factors--for example, physical activity and pain-killing drug injections also cause a rise in total CPK--its clinical usefulness was severely limited.

Now, however, a Stanford medical research team, building on the work of Dr. Frank Elevich of Mt. Zion Hospital and Medical Center in San Francisco, has analyzed the sources of elevated CPK in a heart attack and confirmed the three possible patterns by which CPK leaks into the blood rum.

The researchers have found three sources of CPK elevation--heart, brain and skeletal muscle. One characteristic pattern of CPK rise was found specifically in patients after a heart attack and in those who suffer from muscular dystrophy.

Dr. Paul Wolf, associate professor of pathology and director of the Stanford clinical laboratories, said the test was a sensitive indicator and specific to these diseases. The test is now used in certain types of cardiac and open-heart surgery patients at Stanford.

He said the test will detect whether a heart attack has caused heart muscle damage when it cannot be diagnosed by the electrocardiogram.

The research was reported at the meeting of the American Society of Clinical Pathologists in Chicago. Wolf's collaborators included Dr. James Lauridson, Jeane Albrecht, and Terry Kearns.

Wolf said the test can also be used to identify persons who are sensitive to general anesthesia, and prevent the relatively rare but fatal condition, malignant hyperthermia or hyperpyrexia. This reaction is characterized by a rapid increase of the patient's temperature which cooks the blood vessels.

He said prevention may now be possible by identifying the susceptible individuals. He said recent studies at Stanford and in other centers have shown that this susceptibility runs in families, and detection of raised CPK has indicated these individuals.

Wolf said the test is simple, inexpensive, and can be easily performed in every hospital clinical laboratory by taking a small blood sample and placing it in an electric field instrument. The test result is determined by simple stain of the blood. If heart muscle damage has occurred, only the heart CPK pattern is present.

STANFORD--Dr. W. Maxwell Cowan, an internationally-known expert in the structure and development of the brain and nervous system, has been appointed professor and chairman of the Departments of Anatomy and Physiology at the Stanford University School of Medicine.

His appointment, which culminated a nationwide search, was announced Tuesday (October 23) by Dr. Clayton Rich, vice-president for medical affairs and dean of the Medical School. It becomes effective July 1, 1974.

Dr. Cowan's appointment follows the announcement earlier this year of a $7.5 million grant from the Sherman Fairchild Foundation for the construction of a Center for the Neurosciences at Stanford.

The Center, to be completed in early 1976, will house the Departments of Anatomy and Physiology, as well as research laboratories and classrooms. Both departments are currently in quarters at some distance from the Medical Center.

"We believe," Dr. Rich said, "that a major frontier for important scientific advances in the t decade will be the field of neurosciences--the search for better understanding of the brain and nervous system, the intellectual processes, and mental disorders.

"Because of this fine appointment, construction of the Fairchild Center, and an opportunity to attract additional outstanding faculty members, Stanford is in a unique position to advance the study of the brain."

Dr. Cowan, 42, has been professor and chairman of the Department of Anatomy at the Washington University School of Medicine in St. Louis since 1968.

He is noted for pioneering research on the structure and connections of those parts of the nervous system involved in emotion and memory. Also, his studies of the mechanisms of the nervous systems in avian models have led to a better understanding of the development of the visual system.

His recent research has focused on the problems of how nerve fibers make appropriate connections in the brain during development. He and his associates determined that nerve fibers from the developing eye return to the brain to make connections with appropriate nerve cells, so that the picture of the world seen by the retina is accurately transmitted to the brain.

They found evidence that two mechanisms were at work: growing nerve fibers must have an identifying chemical marker which is recognized by the appropriate target nerve cell; and a first come, first serve, principle seems to exist in the distribution of available cites on target nerve cells.

Dr. Cowan is also investigating the applications of computers to the collection and analysis of anatomical data concerning the brain and nervous system. An automated radiographic method of tracing nervous system pathways was perfected in his laboratory.

-more-

222--W. Maxwell Cowan appointed

A native of Johannesberg, South Africa, Dr. Cowan received the B.Sc. degree from Witwatersrand University in Johannesberg in 1951. He obtained both the Ph.D. in 1956 and the B.M., B.Ch. (equivalent to the M.D.) in 1958 from the University of Oxford in England.

He taught on the staff at Oxford until 1966, when he was appointed associate professor of Anatomy at the University of Wisconsin School of Medicine. In 1968, he became professor and chairman of Anatomy at Washington University, where he had served as a visiting associate professor in 1964 and '65. He was also appointed professor or bioengineering at Washington in 1971.

Formerly managing editor of the Journal of Comparative Neurology, Dr. Cowan is the author of over 60 scientific publications and textbook chapters.

He is a fellow of the Royal Microscopical Society and a member of the Anatomical Society of Great Britain and Ireland, the American Association of Anatomists, and the Society for Neuroscience. In 1971 he was appointed to the Board of Scientific Counselors of the National Eye Institute in Bethesda, Md.

In Stanford's Anatomy Department, Dr. Cowan will succeed Dr. Robert A Chase, professor and chairman of the Department of Surgery, who took over as acting Anatomy chairman when Dr. Donald Gray retired Sept. 1.

In physiology, he will succeed Dr. Maurice Krahl, who will retire next year.

Dr. and Mrs. Cowan have three children--a daughter, 16, and two sons, 14 and 11. They plan to live on or near the Stanford campus.

STANFORD--Seventy-two percent of patients treated by Stanford's medical linear accelerators for cancer limited to the prostate gland survived at least five years after treatment, and 44 percent at least 10 years, two radiologists have reported on the basis of 16 years experience.

In a restrospective study of 405 patients treated at Stanford, this high survival rate was found in patients who malignancy was limited to the prostatic capsule.

However, the radiologists said, cancers that extend beyond the prostate to surrounding tissue are more difficult to treat. In such patients they found a significant decrease in survival--51 percent at 5 years, and 38 percent in 10 years.

Results of the study were presented Saturday (Oct. 20) at the International Congress of Radiology in Madrid, Spain. Authors of the report are Dr. Malcolm A. Bagshaw, and Dr. Gordon R. Ray of the department of radiology of the Stanford University School of Medicine.

According to Bagshaw, survival rates depend on the degree to which lymph glands are involved. "It appears there is better survival for the more limited disease," he said.

To determine more precisely the degree of cancer involvement before a method of radiation treatment is selected, future Stanford patients will undergo special diagnostic procedures as well as surgical staging (exploratory surgery for purposes of diagnosis). The radiologists hope that by defining more precisely the area involved, especially if adjacent lymph nodes are affected, the extended field of radiation treatment will bring about increased cure rates.

"Prostatic cancer is an important malignancy, especially in Caucasians and Blacks," said Bagshaw. "The incidence is equal to colon cancer, and each of these is second only to cancer of the lung as being the most lethal cancer in the male."

Cancer of the prostate kills some 18,000 men annually in the United States. The prostate gland is part of the male reproductive system, lying below the bladder and surrounding part of the canal that empties the bladder.

The disease may produce two quite different kinds of symptoms. One kind, due to the enlargement of the prostate itself, consists of urinary difficulty. The other is pain in other parts of the body, for instance in the lower spine, resulting from spread of the disease to the bones of the skeleton.

While surgical removal of the prostate remains the treatment of choice in a small percentage of carefully selected patients, according to Bagshaw, "for many patients whose tumor, though still localized to the prostate, is too extensive to be cured by surgery, there has been no definitive treatment available."

-more-

It is for these patients, Bagshaw said, "that we believe treatment with external beam radiotherapy has its greatest curative potential."

He added that in cases where the tumor has extended to other parts of the pelvis, radiotherapy is the only treatment that is both widely applicable and potentially curative.

The Stanford radiologists also studied the impact of radiotherapy on potency. Sixty-one percent of the patients who alleged potency before therapy stated they had remained potent after treatment, Bagshaw said.

He stressed that the interval between diagnosis and therapy was relevant to the five-year survival rates, with delay of more than one year having an adverse effect.

He recommended that digital examination of the prostate should be made an unfailing part of every physical examination in the male.

"If the cancer is less than one centimeter in diameter and surrounded by compressible, normal feeling prostatic tissue and relatively low-grade malignancy, surgery may be used," he said.

If, on the other hand, the lesion is more extensive but limited to the prostate, aggressive radiation therapy is the treatment of choice, the radiologist added.

STANFORD -- A government-sponsored panel Wednesday (Oct. 10) warned that operating room staffs may be exposed to potentially serious health hazards.

The panel suspects that chronic exposure to trace amounts of anesthetics that leak into operating rooms may relate to increased incidence of cancer, liver disease, miscarriage, and birth defects. Such contamination has only recently been measured and seems to be present in all operating rooms.

Emphasizing the preliminary nature of the report, the scientists declined to disclose specific incidence figures until the study is finished early next year.

But given the importance of the data, they felt justified to issue a warning, and a statement is being sent to the nation's hospitals urging them to take measures as rapidly as possible to reduce operating room contamination.

Reduction of trace concentrations of anesthetic gases can be achieved by installation of a scavenging system which vents them out of the operating room, the scientists said. Many hospitals have already put such devices in operation.

The report is based on a nationwide epidemiologic survey of operating room personnel. It was scheduled for release later this week in Washington by the National Institute of Occupational Safety and Health (NIOSH) which sponsored the work. However, part of the report was made public Tuesday at the meeting of the American Society of Anesthesiologists (ASA) in San Francisco.

With the assistance of the ASA, American Association of Nurse Anesthetists, Association of Operating Room Nurses, Association of Operating Room Technicians and American Society of Oral Surgeons, a questionnaire was designed and mailed to their members, according to the report. The study was carried out by an ad hoc committee of the ASA headed by Dr. Ellis Cohen, professor of anesthesia at the Stanford University School of Medicine.

Control groups consisted of members of the American Academy of Pediatrics and segments of the American Nursing Association and American Dental Association. These groups normally do not receive chronic exposure to anesthetic agents.

A total of 81,287 questionnaires were distributed, augmented by some 33,000 follow-up letters. To date, 43,173 questionnaires have been returned. The information obtained so far has been entered into computers and is being analyzed by Stanford biostatisticians.

The scientists are careful to point out that showing a relationship between employment in the operating room and an increase in the incidence of miscarriage or other disease is no proof of causation, but they have tried to examine common factors between control and exposed groups.

"Even though human evidence for a cause-effect relationship is not available, we have to assume on the basis of animal experiments that waste anesthetic gases may be responsible," they said.

-more-

Their statement calls attention to these findings:

Miscarriage: Studies of more than 24,500 pregnancies confirm previous reports that exposure of the pregnant woman to the operating room environment increases her risk of spontaneous abortion.

Cancer: Female physician anesthetists may show an increase in susceptibility to cancer, but this is not true for male physicians. Earlier reports that nurse anesthetists have an increased incidence of cancer could not be confirmed.

Liver disease: There is suggestion of a substantial increase in the risk of liver disease among exposed physicians, nurse anesthetists, and oral surgeons. This risk appears equally applicable to males and females.

Birth defects: There is an increase in the incidence of congenital anomalies in children of women who work in operating rooms. The incidence appears related to the degree of operating room exposure.

"The need to assure safe and healthful working conditions for hospital workers is critical," the scientists said.

Presently, federal authorities are evaluating the results of a survey of hospital employee health services. The survey indicates a lack of positive programs to identify early pregnancy and to counsel employees before and during pregnancy about potential hazards to the unborn child, the researchers said.

NIOSH, in cooperation with the ASA ad hoc committee, will recommend standards on waste anesthetic gases including work practices and control procedures for removing them from operating rooms. (A model scavenging device for venting gases out of the operating room has been designed by Stanford professor Charles E. Whitcher, and further investigations in this area are currently being conducted at Stanford.)

Members of the ASA scientific panel are: Ellis N. Cohen, chairman, Stanford; Byron W. Brown, Stanford; David L. Bruce, Northwestern University; Helmut F. Cascorbi, Case-Western Reserve University; Thomas H. Corbett, University of Michigan; Thomas W. Jones, American Society of Oral Surgeons; and Charles E. Whitcher, Stanford.

NIOSH members include Joseph K. Wagoner, Victor E. Archer, Philip Bierbaum, and Jane A. Lee.

STANFORD--Dr. Bruce N. Goldreyer, a prominent researcher in heart disease, will deliver the 10th annual John Kent Lewis Memorial Lecture Monday, October 15, at Stanford University School of Medicine.

His talk, "Paroxysmal Supraventricular Tachycardia--Its Mechanism and Therapy," will begin at 4:15 p.m. in Room M106 at the Medical School.

Dr. Goldreyer, formerly assistant professor of medicine and director of the Medical Intensive Care Unit at the University of Pennsylvania, is clinical assistant professor of medicine at the University of Southern California.

The 32-year old cardiologist is an expert on the electrophysiology of the heart, particularly the geneses and mechanisms of irregular heart rhythms. Paroxysmal supraventricular tachycardia is an abnormally fast heartbeat occurring in sudden attacks.

Earlier this year, Dr. Goldreyer was named an Established Investigator of the American Heart Association. He has authored numerous scientific articles and textbook chapters on cardiac physiology and disease.

A native of Brooklyn, New York, he received his A.B. from Amherst College in 1961 and his M.D. from Columbia University in 1965. He served his internship and residency at the Columbia-Presbyterian Medical Center.

The John Kent Lewis Memorial Lectures are presented in honor of the former chief of the Stanford Medical Service at San Francisco General Hospital. Dr. Lewis was a 1922 graduate of Stanford Medical School. A noted pioneer in heart research, he died in 1961.

STANFORD -- A small house located on hospital grounds has become "home" to many physically handicapped patients and their families at Stanford University Hospital.

The fully-furnished house serves as a temporary residence for patients and families who must learn to cope with a long-term handicap or disability.

Prior to his discharge from the Hospital, the patient and his family move into the house for a transitional two-to-five day period. During this time, family members are trained to perform nursing and physical therapy tasks, such as helping the patient into a wheelchair, turning him in bed, transferring him to a chair, and bathing him.

Having received this training, family members can more effectively manage the patient when they all return home, Stanford physical therapists believe.

The program, called "Family Focus," is the only one of its kind in the country. It was established two years ago by the Division of Physical Therapy at Stanford Medical School. After a year of planning and preparation, the first patient and family moved in 14 months ago.

To date, 27 families have made "Family Focus" their temporary home. During their stay, patients continue to receive all necessary medical services, and 24-hour nursing coverage is provided.

A large number of patients in the program have been elderly individuals, including some suffering from cancer and others learning to walk following total hip replacement. However, the program has also included a four-month-old baby with a damaged respiratory system and a young mother who suffered a stroke and temporary paralysis during childbirth.

"We have had both 'uphill' and 'downhill' patients," says Stanford physical therapist Elaine Hansen. "For the uphill group, which includes many patients recovering from a stroke, accident, or operation, our aim is to increase function.

"The downhill group consists of patients who must learn to adjust to loss of function. This is true for many cancer patients. Here our focus is on the family, and helping them do more for the patient."

The house, located directly behind Stanford Hospital's Hoover Pavilion, consists of a living room, family room with eating area, kitchen, bedroom and bath.

At the same time it functions as a home, the house is a classroom for both the families and interns from Stanfords' Master's Degree program in physical therapy. A second bedroom in the center of the house serves as an observation room. With the family's permission, first-year interns observe treatment and family training sessions.

Each family works directly with Stanford physical therapists and one second-year intern who is given the opportunity to carry out much of the treatment and instruction.

"The interns act as instructors for the patients and families, in addition to providing treatment," says program coordinator Kay Shepard. "They see a different kind of role for themselves in terms of including the family as part of the healing team."

Within a three-month period after discharge, three follow-up visits are made to the patient's home by the intern and his instructor.

The follow-up visits are part of an effort to evaluate the success of the program. "Family Focus" patients will be compared to control patients who were not involved in the program, but had similar handicaps and received follow-up visits on the same schedule.

"Though we are continuing to gather data, our impressions are very positive," Miss Shepard says. "In some instances, physicians referred cases here to demonstrate to family members that they could not handle the patient and shouldn't take him home. But in each instance, the families proved much more capable than expected."

The program has been supported by the U.S. Public Health Service's Bureau of Allied Health Manpower Education. The $72,500 per year grant was originally scheduled to run five years. However, because of cutbacks in federal funding, continuation of the program beyond June of 1974 is uncertain, according to Helen Blood, director of the division of physical therapy at Stanford.

In addition to the physical therapists from the Medical School, the "Family Focus" staff includes psychologists John E. Bell and Norma Davies, who provide consultation in helping the patients and families adjust to the handicap. ###

STANFORD--Two noted professors have joined the faculty of the Stanford University School of Medicine. They are Drs. William Agras, a psychiatrist well known for his work in behavior modification, and Dr. John Nicholls, a neurophysiologist concerned with the relation of the central nervous system to behavior.

Their appointments, effective October 1, were announced by Dr. Clayton Rich, vice president for medical affairs and dean of the Medical School. Dr. Agras is professor of psychiatry, and Dr. Nicholls is professor of physiology.

Former professor and chairman of psychiatry at the University of Mississippi Medical Center, Dr. Agras is an authority on using behavior modification to deal with psychiatric problems. The approach involves helping a patient change his environment or behavior to alleviate symptoms, instead of attempting to understand the causes of his problem through psychoanalysis. The technique was endorsed this year by the American Psychiatric Association.

Dr. Agras, author of numerous scientific publications, is on the editorial boards of several professional journals and is the 1974 editor of the Journal of Applied Behavior Analysis. He has also served on a variety of local and state committees concerned with enhancing mental health services.

A native of England, Dr. Agras, 44, graduated from the Middlesex Hospital Medical School in London, in 1955. Following a year of training in England, he became a psychiatry resident in Canada, first at Montreal General Hospital and then at Montreal Children's Hospital.

From 1959 until 1961, he was a teaching fellow in the Department of Psychiatry at Montreal General Hospital. He subsequently served on the faculty of the University of Vermont College of Medicine for eight years, from 1961 until 1969, when he went to Mississippi.

A neurophysiologist, Dr. Nicholls is interested in how nerve cells work together to produce organized behavior. His studies of the basic mechanisms in central nervous systems in lower animals have contributed to the understanding of the more complex nervous systems of mammals.

Dr. Nicholls, 43, was previously associate professor of neurobiology at Harvard Medical School. Since 1971, he has also been an adjunct fellow of the Salk Institute. He is author of several research publications.

Born in England, Dr. Nicholls received his Ph.D. in physiology in 1955 from London University. After serving as casualty officer at Charing Cross Hospital in London for a year, he did research in physiology at University College, London and at Oxford.

In 1962, he became a research fellow in neuropharmacology at Harvard Medical School. Three years later he joined the faculty of Yale University School of Medicine as associate professor of physiology, where he remained until returning to Harvard in 1968.

STANFORD--Harry Schwartz, member of the editorial board of The New York Times, will be the luncheon speaker at the Big Game Reunion of the Stanford Medical Alumni Association Friday (Nov. 23) in the Palo Alto Holiday Inn.

Schwartz, author of a new book, "The Case for American Medicine," clearly believes that neither a crisis nor even any serious problems exist in American health care, and is therefore skeptical of widely touted proposals for improving it.

In his book, Schwartz not only thinks that medical care in the United States is the world's best, but he challenges those zealous advocates of change whose arguments largely consist of a recitation of horror stories and a damnation of doctors as villains.

Schwartz questions the estimate of a current doctor shortage of 50,000, and argues that available examples of health maintenance organizations (HMO's) should be examined critically before the federal government spawns a string of them across the country.

And it is very useful, according to Schwartz, to compare infant mortality rates in several countries not only in rough totals as is usually done but, among other ways, in terms of population densities. On such a basis he finds that the infant mortality rate of New York City is about the same as that of Moscow or Leningrad.

Schwartz says that the technological marvels of American medicine, exotic as they may sometimes seem, shouldn't be ignored for they are saving thousands of lives.

He also thinks it may be an illusion, as some believe, that changes in the health care system will greatly improve the nation's health, which may be more affected by diet, housing, atmospheric conditions, and education than by medical treatment.

Schwartz does not imply that American medicine is perfect, that the status quo must be preserved intact, or that improvement is impossible. He recommends improvements in two aspects:

Funding a system of catastrophic medical insurance, with "limits to preserve expensive abuses," is not an unreasonable step for the federal government to take.

Training programs in specialties where there is a surplus of doctors should be drastically reduced, and financial incentives should be offered to correct imbalances. The number of neighborhood health centers should be increased. And "the medical profession might designate certain geographic areas that are best supplied with physicians as areas of doctor surplus and attempt to discourage other physicians from moving to the surplus areas for some periods of time."

Following Schwartz's talk, Dean Clayton Rich, vice president for medical affairs and dean of the School of Medicine, will report on medical school facilities and academic planning.

Alumni sessions in the morning will be devoted to presentations by the new chairmen of psychiatry, pediatrics, anesthesia, neurology, radiology and medicine. The morning sessions will be in Room M106 of the Medical School.

STANFORD--Stanford University Medical Center has launched a comprehensive energy conservation program, assistant vice-president for medical affairs Peter Carpenter announced Monday (November 19).

"We intend to minimize energy usage wherever possible," Carpenter said. "At the same time, our top priority is to insure that we have the necessary energy supply to meet our patient care responsibilities and support long-term research projects."

Several steps to conserve energy have already been taken.

The fountains and decorative lights in front of the Medical Center have been turned off, and the hot water temperature on all hot water systems has been turned down, chief engineer James McNally said.

Additionally, all escalators are being shut down from 9 p.m. to 6 a.m., and the Center's corridors are being left on half lighting 24 hours a day, except for nursing units, McNally said.

Two fluorescent light tubes are being removed from all four tube light fixtures, and all non-essential air conditioning is being disconnected, he added. Weekend energy service is being reduced, except for vital patient care requirements.

McNally said that Medical Center officials became aware last spring that an energy crisis was likely this year, and immediately began considering possible conservation measures.

Currently, his staff is making an intensive energy survey of the 1 million square foot center.

"We want to get input from all departments so that, in planning future energy conversation efforts, we do not in any way jeopardize patient care or research activities," he said.

Contemplated future measures include: a shut down of certain extra elevators from 10 p.m. to 6 a.m.; encouragement of employees to remove fans, foot warmers, and coffee pots; removal of electrical cords from unnecessary window air conditioners; and shutting off of circuits at panels where other service is not affected.

Additionally, McNally said, efforts will be made to conserve energy in all future renovation projects in the Medical Center.

The energy resources utilized in the operation of the Medical Center are primarily natural gases, fuel oils, and electricity. Electricity generated by the Bureau of Reclamation hydro-electric dams and power stations is supplied by the City of Palo Alto.

Steam for the Center's heating and hot water needs is provided by the University's Steam Plant. The Plant's main source of power is natural gas from Pacific Gas & Electric. A backup system produces steam by burning fuel oil.

The Hoover Pavilion has its own boilers for the generation of steam and hot water. The primary source of power is natural gas, with fuel oil as the backup system. ###

Editors: The press is invited to attend this symposium. The Children's Hospital is located at 520 Willow Road.

STANFORD--The ninth annual Harold K. Faber Clinical Symposium will be held Friday (Nov. 16) beginning at 9 a.m. in the Children's Hospital at Stanford.

Three papers will be presented at the meeting. Dr. Norman Kretchmer, Harold K. Faber professor of pediatrics at Stanford, will talk on the "Evolutionary Aspects of Human Nutrition." Dr. Louis K. Diamond, professor of pediatrics at the University of California Medical School, will speak on "Splenic Function, Asplenia and Splenectomy."

The Faber lecture, "Who Will Take Care of the Child?" will be presented by Dr. Waldo E. Nelson, professor of pediatrics at Temple University Medical School, Pennsylvania.

Luncheon will follow at the Children's Hospital.
